Number of Residencies, by Hospital Bed Capacities

Excluding hospitals of less than 100 beds, the hospitals offering residency training are, roughly speaking, about equally divided into four categories: 100 to 199 bed capacity, 200 to 299, 300 to 499, and over 500 beds (table 9). The number of residencies in these hospitals, however, varied greatly, with those of 100 to 199 beds offering 1,611 positions, or approximately 6% of the total, and those with over 500 beds having 13,553 positions, or 52% of the total. Hospitals with 200 to 299 and 300 to 499 beds offered an additional 10,762 residencies, or 40% of the total. Hospitals of less than 100 beds and programs in institutions of undesignated bed capacities accounted for the remaining 2%.

Hospitals of less than 100 beds are usually of special type, providing services in one or two specialties, often for only one or two years. They include hospitals for children's orthopedic surgery; eye, ear, nose, and throat; obstetrics; pediatrics; special fields of psychiatry; and similar specialized fields. In these hospitals the admission rate approximates that for a service in a larger general hospital.

While the average number of residencies per hospital may not be too important, it is of some significance in considering the distribution of residents. The averages are as follows: 100 to 199 beds, 7.4 residents per hospital; 200 to 299 beds, 11.5 residents; 300 to 499 beds, 24 residents; and 500 and over, 46 residents per hospital. Since the total number of beds for all hospitals in each category has not been computed, the average number per resident cannot be accurately given. Using the mean number of beds for each category, however, it can be estimated that the number of beds per resident varies from 17 in the 300 to 499 group to 22 in 200 to 299 category. A further variable in considering these rough estimates is, of course, the specialty itself; the number of beds that would be adequate for an obstetric service, for example, would be insufficient to support a program in orthopedic surgery.

On the basis of these incomplete data it appears that the number of residencies is generally in proportion to the size of the hospital. This generalization does not, of course, eliminate the possibility that in individual hospitals the resident may be "overloaded" or the hospital may have a disproportionately large resident staff. It does show, however, that there is, on the average, a reasonable number of beds per resident in the majority of hospitals approved for residency training.

RÉSUMÉ

This report on internships and residencies has presented factual information concerning internships and residencies in hospitals approved by the Council, including an analysis of nine statistical tables and two graphs. Information is also given on the activities of the review committees for internships and residencies; the National Intern Matching Program; the Essentials of an Approved Internship; stipends for interns; autopsy rates; and a brief review of the situation regarding house staff positions occupied by foreign medical school graduates and plans for evaluation of their qualifications. A short statement is included regarding the Sears Roebuck Foundation.

On Sept. 1, 1955, 6,123 intern and resident training programs were sponsored by 1,373 hospitals. Of this total number of hospitals, 171 were approved for the training of interns only, 506 were approved for the training of residents only, and 696 were approved for the training of both interns and residents. Since 1954, there has been an increase of 5% in the number of internships offered, from 11,048 to 11,616. During the same period, there has been a similar increase of 4% in the number of approved residencies, from 25,486 to 26,516.

The percentage of intern positions filled was 83%, as compared with 82% for the year 1954. The occupancy rate for residencies was 81%, as compared with 80% for the previous year. On Sept. 1, 1955, there were 9,603 interns and 21,425 residents on duty in hospitals approved by the Council, a total of 31,028 interns and residents. Fourteen per cent of American physicians are serving as interns and residents in approved hospitals.

It is pointed out that, although the problem of evaluating the qualifications of foreign medical school graduates is presently of great importance, the plan for evaluation of the foreign physician coming to this country for further medical training is expected to become effective within a period of one year. It is anticipated that this program, when in operation, will accomplish much toward the solution of the problems of foreign-trained physicians.

The lists of approved internships and residencies are up to date as of Sept. 1, 1956. It is the sincere hope of the Council that this report will be of value and assistance to those interested in medical education at the internship and residency levels.

ANNUAL REPORT ON APPROVED TECHNICAL SCHOOLS

Medical Record Librarians

Background.—In 1942, the American Association of Medical Record Librarians requested the American Medical Association to evaluate educational programs in medical record library science. The Council formulated standards that were adopted by the House of Delegates of the American Medical Association in June, 1943. Subsequent revisions in standards were made in 1945 and 1949. The first list of 10 approved schools was published in 1944.

With the work done in close collaboration with the committee on education and registration and the education director of the American Association of Medical Record Librarians, who conducts periodic surveys, training programs and new applications are reviewed and recommendatory action is submitted to the Council for final action on approval.

Significant studies in medical record library science to assist the continued development of the field have been initiated during the past year by the American Association of Medical Record Librarians.

Present Status.—At the present time there are 29 schools approved for training medical record librarians, or an increase of 4 schools since Oct. 8, 1955 The 134 students enrolled in the senior class of degree programs and in certificate programs in 1955 represented a total of 19 more students than were in training the previous year. The training capacity of the schools inceased 12% to a total of 269 students during the same one-year period. Similarly, the number of graduates during 1955 was 134, which represents an encouraging increase of almost 18% over 1954.

Depending upon the students' previous education, both degree and certificate recognition are available following satisfactory completion of the required educational program in medical record library science. Among the 20 certificate programs of one year's duration, 15 require two years of college or an R.N. degree, one accepts only students with two years of college, and 4 require a degree prior to admission. Nine schools offer a four-year educational program that lead to a degree and admit qualified high school graduates. In addition there are two degree programs of 12 months' duration that admit qualified students who have completed three years of preparatory college education. Since two schools offer both degree and certificate courses, there are 20 certificates and 11 degree courses available in the 29 approved schools. Only three schools are not conducted by or in affiliation with a college or university.

The beginning dates for courses are predominately in September, several begin in the winter, and a few in June or July. Tuition ranges from $125 to $600, and one school requires none.

Application for approval should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Inquiries regarding the registration of qualified medical record librarians should be addressed to the American Association of Medical Record Librarians, 510 N. Dearborn St., Chicago 10.

Medical Record Technicians

Background.—To alleviate the acute shortage of trained personnel in medical record library science, the American Association of Medical Record Librarians recommended that consideration be given to the establishment of additional training programs for students directly out of high school. In cooperation with the committee on education and registration of the American Association of Medical Record Librarians, the Council developed standards that were approved by the House of Delegates of the American Medical Association in December, 1953. These standards are prepared for the training of the medical record technician who, working under the supervision of a qualified medical record librarian or a medical record committee, performs the technical tasks associated with the maintenance and custody of medical records.

As in the case of schools for medical record librarians, the Council evaluates educational programs and new applications and surveys schools in close collaboration with the American Association of Medical Record Librarians. The training of medical record technicians should be conducted in acceptable general hospitals having a minimum of 4,000 annual admissions. These admissions should include an adequate distribution of patients in the various clinical services commonly found in general hospitals. Candidates for admission to an approved school should be proficient in typing and preferably also in shorthand. They should have completed the requirements for high school graduation or should have passed a college entrance examination for admission to an accredited college or university. The minimum length of training is nine months and should include theoretical instruction in anatomy, medical terminology, and medical records, with additional practical training in admitting and discharge procedures, indexing, preparation of reports, and other activities associated with the medical record department.

Present Status.—There are eight schools approved by the Council for training medical records technicians. These schools report a training capacity for 50 students with an enrollment of 35 in 1955. Qualified high school graduates are accepted for courses of from 9 to 12 months' duration. There were 28 graduates in 1955.

Application for approval should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Special forms will be supplied for this purpose, and, when the required information has been received, the proposed training program will be reviewed in collaboration with the Committee on Education and Registration of the American Association of Medical Record Librarians. The institutions applying for Council approval will, in all instances, receive full information and every possible assistance in the planning and development of training programs in accordance with present standards. There continues to be an acute shortage of qualified medical record librarians and medical record technicians. Excellent opportunities exist for graduating students. Inquiries on career opportunities and the registration of qualified medical record personnel should be addressed to the American Association of Medical Record Librarians, 510 North Dearborn St., Chicago 10.

Medical Technologists

Background.—In 1928 the American Society of Clinical Pathologists established its board of registry of medical technologists in an effort to elevate educational standards for medical technologists. Realizing the need for survey visits to schools, the society requested the Council on Medical Education and Hospitals of the American Medical Association to aid in the study of training programs in 1933. Essentials of an acceptable school were formulated by the Council with the cooperation of the society and ratified by the House of Delegates of the American Medical Association in May, 1936. The first list of 96 schools approved by the Council was published in The Journal on August 29, 1936.

In its efforts to assist hospitals in the development of training programs, the Council has continuously cooperated with the American Society of Clinical Pathologists, the board of schools of medical technology, and the board of registry of the society. The board of schools was established by the society in 1949 to serve in an advisory capacity to the Council in matters relating to standards and the evaluation of educational programs. Revisions of the standards occurred in 1941, 1943, 1947, 1949, and 1953. In 1956, the requirement for training in electrocardiographic technique was deleted from the curriculum in the "Essentials of an Acceptable School of Medical Technology." The Board and Council encourage that such training be continued when the pathologist-director considers it advisable.

The board of schools assists the Council in the evaluation of new applications and annual reevaluations of approved schools. A survey program is carried out by regional surveyors appointed by the board of schools. These pathologists visit all new schools and, in addition, periodically revisit approved schools. An extensive resurvey of existing educational program is actively in progress by pathologists appointed by the Board who make an invaluable contribution to the program in experience and time. The recommendations of the Board on new applications and existing schools of medical technology are submitted to the Council for its consideration.

Present Status.—There are 618 schools presently approved by the Council, or an increase of 4% over the 593 approved as of Oct. 8, 1955. This is a net increase of 25 training programs, representing 36 newly approved schools and 11 that have been discontinued or disapproved. The 1955 student enrollment has risen 17% to 2,790, as compared with the 2,384 reported for 1954. The occupancy rate in 1955 was 62% in programs having a training capacity for 4,532 students. The number of graduates continues to increase. There were 1,956 in 1954 and 2,078 in 1955. It should be noted that the increases in student enrollment, occupancy rate, and number of graduates reflects the concerted recruitment efforts of the many persons associated with the College of American Pathologists, American Society of Clinical Pathologists, American Society of Medical Technologists, and the National Committee for Careers in Medical Technology, sponsored by these organizations, as well as the recruitment activities of the faculties of approved schools and affiliated colleges and universities.

The admission requirement to an approved school of medical technology is two years of college education, including certain required courses, in a college or university accredited by a recognized association. Eighty-one per cent or 500 training programs base admission on this minimum requirement; 71 (11%) require three years of preclinical college education; and 47, or 8%, require a degree for admission.

There has been an increase in the number of hospital schools that have affiliated with colleges and universities. Such affiliations are encouraged, since they assist in the development of well-organized training programs suitably integrated with the college curriculum and also serve as a continuing source of students. A total of 423 hospital schools (68%) have established college or university affiliations. College credit is granted for the hospital training in 385 schools. If properly integrated, a degree is available upon competion of three years of college education and one year of hospital training. While the preparatory collegiate education is longer in duration, it is the hospital course that is directly concerned with the technical training of medical technologists. The hospital should assume full responsibility for the 12-month course. Active liaison with the college is recommended through regularly scheduled meetings of a jointly constituted advisory or coordinating committee. At present only 45% of schools so coordinate.

The minimum duration of the hospital course acceptable for approval is 12 months. There are now 542 schools, or 88%, providing a course of 12 month duration. The remaining 76 schools (12%) offer pr grams of from 12½ to 36 months.

Tuition is required by 157 (25%) and a minim breakage fee by 79, or 13%, of the schools. Studen receive a stipend in 256 (43%). Room and board a offered in 171 (28%), board, often consisting lunches only, in 142 (24%), and 3 schools offer roo only. The remaining 297 (48%) offer neither roo nor board.

There were eight states in which schools graduat 75 or more students in 1955. Table 10 presents son aspects of the educational activity in the schools these eight states, arranged in order of number schools.

All states, the District of Columbia, the Canal Zon Hawaii, and Puerto Rico have approved schools.

Application for approval of a school for the traini of medical technologists should be made to the Cou cil on Medical Education and Hospitals of the Ame can Medical Association, 535 N. Dearborn St., Chica 10. Forms will be supplied for this purpose on reque and should be completed by the director of the labor tory requesting this approval. Inquiries regarding t registration of qualified medical technologists shoul be addressed to the Board of Registry of Medic Technologists, 611 W. Howard St., Post Office Bo 1209, Muncie, Ind.

Occupational Therapists

Background.—In 1933, the American Occupation Therapy Association requested the House of Delegate of the American Medical Association to undertake survey of educational programs for occupationa therapists. The Board of Trustees instructed the Coun cil on Medical Education and Hospitals to develo standards and survey existing schools. The "Essentia of an Acceptable School of Occupational Therapy were first published in THE JOURNAL, May 4, 1935. Th first list of six approved schools appeared in 1938. Th Essentials were revised in 1938 and 1949 in coopera tion with the advisory groups to the Council on Med ical Education and Hospitals at that time.

These groups were the Council on Physical Medicine and Rehabilitation of the American Medical Association and the American Occupational Therap Association. In 1955, the Council on Physical Medicine and Rehabilitation became the Council on Medical Physics, and, although close liaison continues, it no longer functions in an advisory capacity on occupational therapy educational matters. New applications are reviewed by physician advisory groups and the American Occupational Therapy Association, surveys are conducted, and recommendatory action is submitted to the Council on Medical Education and Hospitals for action.

Increased attention is being given to procedures for more frequent periodic reevaluation of existing educational programs. Joint physician-therapist survey teams are being planned in close cooperation with the American Occupational Therapy Association to assure continuing liaison with the schools. The American Occupational Therapy Association, with the assistance of other organizations, has foresightedly initiated conferences and basic studies with which to better plan for the needed expansion in the field.

Present Status.—There are currently 30 schools approved by the Council for training occupational therapists. Since the U. S. Army occupational therapy course has been put on a stand-by basis and is not listed as an active program, there were 29 schools accepting students in 1955. All data are based on reports from the 29 active schools. These institutions reported 1955 enrollments as follows: senior class degree (460); postdegree certificate (134); nondegree certificate (5); master's degree (19); and 477 students in their clinical year. Student capacity for these several courses is 731 for the senior class degree, 235 for the postdegree and nondegree certificate, approximately 72 for the master's degree, and not limited in the clinical year. It is encouraging to note that the total enrollment of 618 and a student capacity of more than 1,038, exclusive of the clinical year, reflect gradual but continuing increases in the number of students in training and the training potential of these 29 approved schools. Graduates numbered 551 as compared with 489 in 1954 which continues the upward trend over the past several years. It should be noted that three schools in the process of reorganization or organized within the past several years reported no graduates but can be expected to graduate students in the near future.

Both certificate and degree recognition are available in occupational therapy, depending upon the type and integration of the student's preparatory collegiate training prior to his entering the professional curriculum. Certificate programs, generally of 18-24 months' duration, are offered by 19 schools that, in all but one instance, require a degree for admission. Educational programs of four to five years that lead to a degree are available in 23 schools that will admit qualified high school graduates. Four schools offer degree programs of approximately two years' duration to qualified applicants with two years of preparatory collegiate education. Interested undergraduate students are encouraged to contact individual schools, however, to determine the specific requirements of a given school for admission to its certificate or degree course in occupational therapy. Tuition varies in accord with university fees. The majority of courses begin in February and September.

Application by schools for approval of an educational program in occupational therapy should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Forms will be supplied for this purpose on request. They should be completed by the administrator of the institution requesting approval. Inquiries regarding career opportunities in the field of occupational therapy and the registration of qualified therapists should be addressed to the American Occupational Therapy Association, 250 W. 57th St., New York 19.

Physical Therapists

Background.—From 1928 to 1936 the approval of educational programs in this field was sponsored by the American Physical Therapy Association. On request of that association, the Council developed standards that were adopted by the House of Delegates and published with the first list of approved schools in 1936. The Council, in cooperation with its advisory groups, the Council on Physical Medicine and Rehabilitation of the American Medical Association and the American Physical Therapy Association, has periodically submitted revised standards to the House of Delegates, which were adopted in 1943, 1949, and 1955. The most recent revision is the result of four years of intensive discussion and study. In 1955, the Council on Physical Medicine and Rehabilitation became the Council on Medical Physics, with which there continues close liaison on matters pertaining to physical therapy but which no longer functions in an advisory capacity on physical therapy education. Applications of new schools are reviewed in collaboration with two groups, the recently appointed Advisory Committee on Physical Therapy Education of the Council on Medical Education and Hospitals, and the American Physical Therapy Association. The Advisory Committee on Physical Therapy Education consists of nine physician members representing the fields of physical medicine and rehabilitation, orthopedic surgery, psychiatry and neurology, internal medicine, pediatrics, general surgery, and medical education. In addition, there are three physical therapists, two nominated by the American Physical Therapy Association and one nominated by the American Registry of Physical Therapists. Surveys of new and existing schools are conducted by joint physician-therapist teams and recommendatory action submitted by the advisory groups to the Council for action. Active liaison with the medical directors, therapist educational administrators, and other members of the teaching faculties in approved schools is being implemented through more frequent periodic surveys.

Present Status.—There are, at present, 37 schools approved by the Council for training physical therapists, or an additional two schools since Oct. 8, 1955. The student training capacity for the senior class of degree programs and in certificate programs was 1,068 on the basis of 1955 annual reports. In addition, there was an estimated training capacity for at least 86 master's degree students. The 1955 enrollment for senior degree and certificate students was 748 students, or 70% occupancy. Intensive recruitment continues the upward trend in enrollment noted over the past several years. The number of degree and certificate graduates has increased significantly to 710, as compared to 609 in 1954. Unfortunately, data are not available on the increasing number of graduates in the master's degree programs offered in nine schools.

Certificate and/or degree recognition in physical therapy is available depending upon the students' preparatory education prior to entering the professional curriculum. Most schools offer both degree and certificate programs, although seven offer only the certificate program and seven others only the degree program.

Certificate programs in 30 schools vary in length from 12 to 34 months and admit students with two or more years of college or those who have graduated from a nationally accredited school of nursing after a three-year course. Many of the 30 degree programs of four years' duration admit qualified students directly out of high school. Degree recognition in physical therapy is offered to qualified students with two to three years of collegiate education upon satisfactory completion of degree programs of shorter duration. Since admission requirements vary in individual schools, interested high school students and those with two or more years of college or who have graduated from a nationally accredited professional school of nursing should contact the individual school of their choice for specific requirements. The tuition in all teaching centers closely parallels college fees. Most courses begin in February or early fall.

Application for approval should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Forms will be supplied for this purpose on request. They should be completed by the administrator of the institution requesting this approval. Inquiries regarding voluntary registration of qualified therapists should be addressed to the American Registry of Physical Therapists, 30 N. Michigan Ave., Chicago 2. Information on requirements for state registration or licensure is available from the Board of Examiners of the states concerned. Inquiries regarding careers in the field of physical therapy should be addressed to the American Physical Therapy Association, 1790 Broadway, New York 19.

X-Ray Technicians

Background.—Prior to 1944, the approval of schools of x-ray technology had been carried on as a function of the American Registry of X-Ray Technicians. In 1943, the Council on Medical Education and Hospitals of the American Medical Association undertook the evaluation of educational programs for x-ray technicians at the request of the registry, which is sponsored by the American College of Radiology and the American Society of X-Ray Technicians. With the assistance of the college and the registry, standards were developed and adopted by the House of Delegates of the American Medical Association in June, 1944, and December, 1955. The most recent revision of the standards has been developed in close cooperation with the advisory groups and incorporates a suggested basic curriculum, which is presented as a guide. Particularly encouraged is progressive training in therapy to afford students at least one month's practical experience intramurally or through affiliation.

The Council has been ably assisted by the American College of Radiology, the American Registry of X-Ray Technicians, and the American Society of X-Ray Technicians. Schools making application for approval are surveyed by state and regional councilors appointed by the American College of Radiology. Approved schools are also periodically resurveyed by radiologists appointed by the college, and these radiologists are currently revisiting approved schools. Their generous contribution of time and experience are a major asset in the program. All data are reviewed by the advisory committee to the American Society of X-Ray Technicians of the American College of Radiology and recommendations submitted to the Council for consideration.

Present Status.—At present there are 456 schools approved by the Council on Medical Education and Hospitals for training x-ray technicians. This represents a net increase of 34 schools, or an increase of 8% over the number approved as of Oct. 8, 1955. There has been a 307% increase in the number of approved schools since the first published list of 112 in 1945. Enrollment has increased 302, or 12%, to a total of 2,915 students during the last year, in which total training capacity has risen to 3,555 from 3,184, or an increase of 11%. The number of graduates in 1955 was 1,822 as compared with 1,523 in 1945, a 20% increase.

The minimum admission requirement is high school graduation or the passing of a standard equivalency test. A total of 433 schools (95%) admit students directly out of high school, 13 schools (3%) require one year of college, 9 schools (2%) require two years of college, and one school accepts only R.N.'s. Of the above 456 schools, 3 will accept an applicant with either an R.N. or two years of college and, as noted, one school accepts R.N.'s only.

The length of training in 241 (53%) is 24 months, 12 months in 144 (32%), 18 months in 69, or 15%, and 36 months in two schools. Tuition is required by 172 (38%) of approved schools and 60% pay students a stipend. There are collegiate affiliations established in 168 schools (37%). College credit is granted for training satisfactorily completed in the hospital training program in 14%, or 66 schools.

There are 40 approved schools in Illinois, 34 in Pennsylvania, 29 in Ohio, 25 in Texas, 24 in California, 21 in Michigan, 20 in New York, 19 in Missouri, 18 in Massachusetts, 16 each in Minnesota and Wisconsin, and 12 or fewer in all but one of the remaining states, the District of Columbia, and Hawaii. One state does not have a school.

Applications for approval of schools of x-ray technology should be submitted to the Council on Medical Education and Hospitals of the American Medical Association, 535 N. Dearborn St., Chicago 10. Inquiries regarding registration of qualified x-ray technicians should be addressed to the American Registry of X-Ray Technicians, Metropolitan Building, Minneapolis 1.

APPROVED INTERNSHIPS

Council on Medical Education and Hospitals of the American Medical Association
535 North Dearborn Street, Chicago 10

Revised to September 1, 1956

HOSPITALS, 862, INTERNSHIPS, 12,013

The following general hospitals, investigated and approved by the Council on Medical Education and Hospitals, are considered in position to furnish acceptable intern training in accordance with standards adopted by the American Medical Association. Three types of internships are approved by the Council—rotating, mixed, and straight:

1. A rotating internship is defined as one that provides supervised experience in internal medicine, surgery, pediatrics, obstetrics, and their related subspecialties, together with experience in laboratory and radiologic diagnosis.
2. A mixed internship is defined as one that provides supervised experience in two or more, but not in all, of the clinical divisions named.
3. A straight internship is defined as one that provides supervised experience in a single department, although it may include limited opportunity for work in a related subspecialty. Straight internships are now approved in internal medicine, surgery, pediatrics and pathology.

Hospitals approved for internships that are used by medical schools for undergraduate clinical clerkships on inpatient services have been identified in the following lists by the symbols X and x. Hospitals have been identified with symbol X when a medical school has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with the symbol x when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program. Certain internships in hospitals designated as teaching hospitals may not provide for assignments to teaching services. Other internships may provide for only a portion of the internship period being spent on teaching services. Prospective interns desiring specific information concerning internship assignments to teaching services in a hospital are ~~advised~~ to communicate with the dean of the medical school with which the hospital is affiliated. Medical school affiliations are indicated by footnotes 10 to 89 placed immediately after the symbol X or x. The list of medical schools appears on page 312. The plus (+) sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies and Fellowships. The beginning stipends for Federal hospitals have not been listed; they are established in accordance with government pay tables. When applying for internships in Air Force, Army, Navy or Public Health Service hospitals, applications should be directed to the medical departments of the Air Force, Army, Navy, or the United States Public Health Service and not to the individual hospitals. Although applications are made to the service rather than to the individual hospitals, all of the services ask students to list three hospitals in order of preference. Every possible effort is made to place successful candidates in accordance with their desires. Because of the needs of the service it should be understood that students may, in some instances, be assigned to other hospitals than those for which they have indicated a preference.

Hospitals listed below (pages 291 to 311) make first year internship appointments through the National Intern Matching Program, Inc. The number and type of internships as listed represent appointments for the intern year 1957-1958.

HOSPITALS APPROVED FOR INTERNSHIPS IN THE *DOMINION OF CANADA*

The following list of hospitals that conform to the *standards of the Canadian Medical Association* is published for the *information* of graduates interested in an internship appointment in a *Canadian* hospital. Hospitals that are unqualifiedly approved as conforming to the standards of the Canadian Medical Association *may be considered* as offering internships equivalent in *educational* value to those in hospitals approved for intern training by the Council.

This list, revised to Sept. 1, 1955, was furnished by the Canadian Medical Association. *(Sept. 1, 1956, revision* not yet available.)

Name of Hospital	Location
St. John's General Hospital	St. John's, Nfld.
Camp Hill Hospital	Halifax, N. S.
Halifax Infirmary	Halifax, N. S.
Victoria General Hospital	Halifax, N. S.

ABBREVIATIONS AND NOTES

1. Appointments available to women applicants
2. Appointments restricted to women applicants
3. Appointments available to graduates of foreign medical schools. Details regarding requirements for appointment can be secured from the hospitals concerned.
4. Dental internships available
5. Available to citizens of the United States only
6. General Practice internships

+ The plus sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies and Fellowships

CyCo	City and County
Corp	Corporation unrestricted as to profit
Dist	*Hospital District*
NPCorp	*Nonprofit corporation*
Part	*Partnership*
Req	Required
FM	Full maintenance
PM	Partial maintenance

Medical School Affiliations

Footnotes 10 to 89 refer to medical schools affiliated with hospitals for undergraduate clinical clerkships.

Hospitals have been identified with symbol **X** when a medical school has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with symbol **x** when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program.

APPROVED RESIDENCIES AND FELLOWSHIPS

Council on Medical Education and Hospitals of the American Medical Association
535 North Dearborn Street, Chicago 10

Revised to September 1, 1956

Hospitals, 1,211: Assistant Residencies and Fellowships, 27,835

The following services are approved by the Council on Medical Education and Hospitals as meeting the requirements of the Essentials of Approved Residencies and Fellowships. In those specialties in which certifying boards have been established approval is extended in concurrence with the Board concerned as indicated. The number of years of training for which approval has been granted is indicated in the column, "Length of Approved Program (years)." Residencies in which this designation does not appear have been approved without specifying the number of years for which they are accredited. The beginning stipends for Federal hospitals have not been listed; they are established in accordance with government pay tables.

Residency programs in the following hospitals have been approved by the Council and the American Board of Ophthalmology through the Residency Review Committee for Ophthalmology, as offering training of ONE year's duration. It should be noted that beginning July 1, 1957 only those hospitals which either intramurally or through affiliation are able to provide at least two years of clinical training in the specialty, will continue to be approved. These residency programs will be reviewed prior to July 1, 1957 relative to their qualifying for continued approval.

15. ORTHOPEDIC SURGERY

Type of training acceptable to Board: A—Adult orthopedics; C—Children's orthopedics; F—Fractures. Residency programs in the following hospitals have been approved by the Council and the American Board of Orthopedic Surgery, through the Residency Review Committee for Orthopedic Surgery, as offering acceptable training in adult orthopedics, children's orthopedics, and fractures. Training in the basic sciences is given either as an integral part of these services or as a separate course. Services collaborating in an integral plan of training are designated by a program number, a list of which is found on pages 349 and 350. Residents completing their training in these hospitals are eligible for full certification by the American Board of Orthopedic Surgery, including children's orthopedic surgery.

Residency programs in the following hospitals have been approved by the Council and the American Board of Orthopedic Surgery, through the Residency Review Committee for Orthopedic Surgery, as offering acceptable training in adult orthopedics and fractures. *Training in the basic sciences* is given as an integral part of these services or as a separate course. Services collaborating in an integral plan of training are designated *by a* program number, a *list of which* is found on pages 349 and 350.

Residents completing their training in these hospitals are eligible for limited certification *by the American Board of Orthopedic Surgery*, not to include children's orthopedic surgery.

17. PATHOLOGY

Residency programs in the following hospitals have been approved by the Council and the American Board of Pathology. Services which have been evaluated on the basis of training in the two categories, pathologic anatomy and clinical pathology, are designated as follows: a—pathologic anatomy only; c—clinical pathology only; p—pathologic anatomy and clinical pathology. Training in hospitals which are not so designated in this list will be evaluated by the Board on an individual basis at the time of application for certification.

Hospitals, 605; Assistant Residencies and Residencies, 2,109

21. PREVENTIVE MEDICINE AND PUBLIC HEALTH

Residency programs in the following states have been approved for TWO years of training by the Council and the American Board of Preventive Medicine and Public Health, through the Residency Review Committee for Preventive Medicine and Public Health.

PRTVENTIVE MEDICINE AND PUBLIC HEALTH

Department of Health	Location	Director	Local Areas	Population	Stipend (Month)
State of California	Berkeley	M. H. Merrill	Alameda County (a)	244,700*	$458 max.
			Monterey County	164,400*	....
			Orange County	346,200*	....
State of Delaware	Dover	F. I. Hudson	Kent and New Castle Counties (b)	184,000*	$400-500
State of Florida	Jacksonville	W. T. Sowder	Alachua County	62,441*	$500 (c)
			Dade-Miami	691,244*	....
			Hillsborough-Tampa	323,023*	....
			Pinellas-St. Petersburg	207,066*	....
State of Illinois	Springfield	R. R. Cross	Cook County (d) (e)	743,988	$416-500
			Will County (e)	134,366	....
State of Kansas	Wichita	T. R. Hood	Kansas City-Wyandotte	189,000	(f) (g)
			Topeka-Shawnee	115,006	....
			Wichita-Sedgwick	297,388	....
State of Maryland	Baltimore	P. F. Prather	Anne Arundel County	143,126	(g)
			[illegible] County	330,358	....
			[illegible]ict		
			[illegible]	333,000*	....
			[illegible]	206,657	....
			[illegible]	84,161	....
State of Massachusetts	Boston	S. B. Kirkwood	(h)	(h)	
State of Michigan	Lansing	A. E. Heustis	Calhoun County	123,230	$400
			Detroit	1,966,270	....
			Kalamazoo City-County	136,460	....
			Michigan Dept. of Health	(m)	....
			Wayne County (j)	531,710	....
State of Minnesota	Minneapolis	A. J. Chesley, Secy. and Ex. Off.	Olmstead-Rochester	47,728*	75% of what job will pay (k)
New York City	New York City	H. P. Kandle, Dep. Com.	(n)	8,010,000*	$443
State of New York	Albany	H. E. Hilleboe	(l)	(l)	$475
State of North Carolina	Raleigh	J. W. R. Norton	Charlotte-Mecklenburg County.	211,754*	....
			Forsyth-Winston-Salem	152,524*	$500
			Halifax	58,981*	....
			Orange-Person-Chatham-Lee	112,955*	....
State of Oregon	Portland	H. M. Erickson	Multnomah County	119,810*	$500 (i)
State of Texas	Austin	F. C. Kluth	....	....	$700
State of Virginia	Richmond	R. G. Beu	[illegible] County	155,000*	$700
State of Washington	Seattle	B. Bucove	[illegible]	773,900*	$500
			[illegible]	90,600*	....
			Tacoma-Pierce	301,700*	....

---

* *Estimated.*

(a) Excludes Alameda, Berkeley, and Oakland cities with full-time health officers, and Albany with part-time officer.

(b) Excludes the city of Wilmington.

(c) To those planning to work in state; transportation costs only to others.

(d) Excludes Berwyn, Chicago, Evanston, Oak Park, Stickney Township, and Winnetka (including Glencoe, Kenilworth, Northbrook, and remainder of New Trier Township), all with full-time health officers.

(e) Assistance can be arranged for securing the MPH degree in the midst of, or after completion of, residency experience. Appointments normally are limited to those training for service in Illinois.

(f) Arrangements for remuneration made on an individual basis.

(g) *Arrangements for remuneration made upon determination of field of interest and location desired.*

(h) Training is given in a combination of one county, one union health, and seven municipal health departments and in the *divisions of the State* Department of Health.

(i) Assistance can be arranged for securing the MPH degree *after successful* completion of residency experience. Appointments will be limited to those training for service in Oregon.

(j) Excludes Detroit and Dearborn, each with full-time health officers.

(k) To those training for service in Minnesota only.

(l) *Training is given in any one* of 10 city health departments, 16 county health departments, or 15 district offices within the state.

(m) Training to be with Michigan Department of Health, with field experience in local health departments.

(n) Includes training at Montefiore Hospital.

Numerical and other references will be found on pages 387 through 390.

22. PROCTOLOGY

Residency programs in the following hospitals have been approved by the Council and the American Board of Proctology, through the Residency Review Committee for Proctology, as offering acceptable training in the specialty.

Hospitals, 13; Assistant Residencies and Residencies, 29

25. RADIOLOGY

Residency programs in the following hospitals have been approved by the Council and the American Board of Radiology, through the Residency Review Committee for Radiology. As indicated in the column "Type of Training," approval has been extended in diagnostic roentgenology (D.R.); roentgenology (Roent.), including diagnostic and therapeutic; therapeutic radiology (Ther. Rad.), and Radiology (Rad.), including roentgenology and therapeutic radiology. After June 30, 1957, the Residency Review Committee for Radiology will not approve services which are not part of programs providing full training in all branches of the specialty. Some of the programs listed below as approved in limited fields do, through affiliation, offer three years of training in Radiology. This listing is now being revised. Until the revised list is published, prospective applicants are advised to correspond directly with the individual hospitals relative to affiliate training.

28. UROLOGY

Residency programs in the following hospitals have been approved by the Council and the American Board of Urology, through the Residency Review Committee for *Urology*, as offering training of three years', two years' or one year's duration. It should be noted that beginning July 1, 1957 only those hospitals which, either intramurally or through affiliation, are able to *provide full* training in the specialty will continue to be approved. Those hospitals which have residency programs approved for one or two years of training will be reviewed prior to July 1, 1957 relative to their qualifying for continued approval.

Hospitals, 223; Assistant Residencies and Residencies, 666

FEDERAL

★ Indicates hospitals approved for training interns.

lished in 1955 by the A. N. Marquis Company, Chicago, contains biographic information on the educational background of each living specialist, including those retired from practice, certified by an American board.

Credit for Military Service

At the suggestion of the Joint Committee on Medical Education in Time of National Emergency, the Advisory Board for Medical Specialties conducted a survey to determine the amount of credit for service in the armed forces that would be given toward specialty board certification. The inquiry addressed to the boards contained the following questions:

> Will your specialty board give preference to those candidates wishing to be examined before going overseas or entering military service?
>
> How much, if any, credit toward your training and/or experience requirements will your board allow candidates while in military service?

In reply to the first question all boards answered in the affirmative. The specialty boards have not lowered their requirements because of military emergency, but all boards except one have indicated they will grant some credit for military service. The specialty boards have indicated such allowances as follows:

Table 2.—*Annual Specialty Board Certification, 1941-1956*

Year (Ended March)	No. of Boards in Existence	No. Certified	Cumulated Totals
1941	15	2,085	17,938
1942	15	1,756	19,694
1943	15	2,172	21,866
1944	15	1,578	23,444
1945	15	1,308	24,752
1946	15	1,320	26,072
1947	15	2,424	28,496
1948	16	3,002	31,498
1949 (June 30)	19*	4,479	35,977
1950 (June 30)	19	3,827	39,804
1951 (June 30)	19	4,552	44,346
1952 (June 30)	19	4,118	48,464
1953 (June 30)	19	4,022	52,486
1954 (June 30)	19	4,133	56,619
1955 (June 30)	19	3,843	60,644
1956 (June 30)	19	3,083	63,727

* One board, the American Board of Proctology, did not certify any candidates during this period.

Anesthesiology.—No formal training credit is granted for military service unless the physician is assigned to a service hospital with an approved residency training program. Practice time will, however, be granted for military service if the physician is assigned to the anesthesiology service.

Dermatology.—Students in training who have served as physicians in the Army, Navy, or U. S. Public Health Service may submit a supplementary application, obtainable from the executive secretary, for possible credit toward experience. This application is not obligatory, but if submitted it must be done prior to or at the time of filing application for examination. It will not be considered until the preliminary registration has been filed. Since the application must be circulated through a committee whose members may be widely separated, several months are often required for a decision. Full-time dermatological military service may be credited in some part toward training, at the discretion of the board, provided it was under the direct supervision of a recognized specialist and provided a significant portion of approved training was completed before the service concerned. The board strongly urges that the candidate supplement his military service by further approved dermatological training before examination. Medical service in the armed forces not credited as training may be credited in part toward the two years of additional dermatological experience required for certification, the amount of credit depending on the circumstances.

Internal Medicine.—Active duty as a commissioned officer in the armed forces of the United States from June 1, 1950, to July 1, 1954, may be applied as one year of residency credit or one year of practice credit regardless of assignment. Service beyond one year during this interval may only be applied as practice credit on certification by former chiefs of service that assignments of candidates were in the field of internal medicine on a full-time basis in the care of clinical patients largely on their own responsibility. Active duty in the armed forces as a commissioned officer after July 1, 1954, may not be applied as residency credit unless the candidate has served officially as a resident in a hospital approved for residency training by the Council on Medical Education in internal medicine or in the medical subspecialties recognized by this board. Active duty in the armed forces as a commissioned officer after July 1, 1954, may be applied as practice credit for one year or more on certification by present or former chiefs of service that assignments were in the field of internal medicine on a full-time basis, in the care of clinical patients largely on one's own responsibility. The requirements governing residency credit and practice credit for active duty in the armed forces from Dec. 8, 1941, to Jan. 1, 1947, will remain the same as those governing credit from June 1, 1950, to July 1, 1954, as outlined above.

Neurological Surgery.—The board makes no specific statement regarding military service. This matter is taken up individually with each applicant.

Obstetrics and Gynecology.—Credit will be given for time spent in an obstetric-gynecologic service in an Army or a Navy hospital under supervision on the same basis as a preceptorship, if these departments are supervised by diplomates of the board or recognized obstetricians-gynecologists. Full residency credit may be obtained if such hospital is approved for residency training. The board will review and give consideration to each individual case. Special request must be made for such credits.

Ophthalmology.—No stated credit. Each case is decided according to the time the candidate has spent assigned to a military hospital in ophthalmology and on other factors.

Orthopedic Surgery.—Up to one year of residency credit is given. Each case is determined on its own merits.

Otolaryngology.—Credit is given, but each case is determined on its own merits.

Pathology.—Allows liberal credit toward training when assigned to department of pathology, but candidates must first have had a minimum of one year residency in an approved civilian department of pathology.

Pediatrics.—One year of credit, regardless of assignment, toward two-year practice requirement.

Physical Medicine and Rehabilitation.—Credit is given, but each case is determined on its own merits.

Plastic Surgery.—Credit is given on individual basis, considered on candidate's merits.

Preventive Medicine.—Credit for training and experience in public health or aviation medicine while in military service will be considered on an individual basis, depending on the type of service.

Proctology.—At present no credit is granted for military service.

Psychiatry and Neurology.—For military duty after Jan. 1, 1954, only experience credit will be granted for full-time psychiatric and/or neurological duties. Training credit will be granted for residency assignments in regularly approved training programs.

Radiology.—Maximum of one year's credit if assigned to full time radiological duties.

Surgery.—If a candidate has served in a government hospital or hospitals fully approved for residency training, such training will be acceptable to the board. Military credit may be extended to those candidates who have served in nonapproved hospitals provided that the candidate has had a satisfactory surgical assignment with adequate and diversified clinical material and provided further that his work in surgery is carried out under the supervision of a surgeon acceptable to the board. Any credit extended in the latter category will be considered preceptorship credit and not residency credit.

Thoracic Surgery.—Credit for military service will be decided on an individual basis.

Urology.—No credit for training but credit for one year of practice requirement if training was complete when entering service.

Medical Officer's Professional Training Record.—The surgeons general of the armed services have distributed a booklet prepared with the assistance of the Council and the Advisory Board for Medical Specialties that is designed to help prospective candidates for certification to maintain an accurate account of work done in the military service. This record will constitute part of the credentials to be submitted to the board on application for certification. The booklet has been printed by the Office of the Secretary of Defense and is distributed by the offices of the surgeons general to the personnel of their departments. It is highly important that prospective applicants obtain a copy of the "Medical Officer's Professional Training Record" and that they submit their credentials for evaluation by the respective specialty board.

REFERENCE: J. A. M. A. 159:444-445 (Oct. 1) 1955.

The major changes in requirements for certification are under Certification, paragraph 2: Requirements: Substitute following (1) and (2) under A:

2. *Requirements*

A. Each applicant, before he shall become eligible for certification in anesthesiology, must:

1. Have graduated from an approved medical school in the United States or Canada or have successfully completed the examinations of the National Board of Medical Examiners. Applicants must have completed an internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association, or its equivalent. Graduates of class B medical schools are not eligible to take the board examinations.

2. Establish in a manner satisfactory to the board that (a) he is a physician duly licensed by law to practice medicine, (b) he is of high ethical and professional standing, and (c) he has received adequate special training in anesthesiology.

Under Certification, paragraph 3, Examinations, Insert following paragraph B:

The expense of surveying and/or giving practical examinations outside of the United States will be borne by the candidate. The approximate amount of such funds to be paid by the candidate will be determined by the Secretary and must be paid in United States currency to the American Board of Anesthesiology in advance.

AMERICAN BOARD OF DERMATOLOGY

(Formerly American Board of Dermatology and Syphilology)

Arthur C. Curtis, Ann Arbor, Mich., President
John H. Lamb, Oklahoma City, Vice-President
Nelson Paul Anderson, Los Angeles
J. Lamar Callaway, Durham, N. C.
Marcus R. Caro, Chicago
Clinton W. Lane, St. Louis
Walter C. Lobitz Jr., Hanover, N. H.
Francis W. Lynch, St. Paul
Beatrice Maher Kesten, 1 Haven Ave., New York 32, Secretary-Treasurer

Advisory Members

Anthony C. Cipollaro, New York
Harold N. Cole, Cleveland
Charles C. Dennie, Kansas City, Mo.
George M. Lewis, New York
Henry E. Michelson, Minneapolis
Donald M. Pillsbury, Philadelphia
Francis E. Senear, Chicago
Bedford Shelmire, Dallas, Texas
Arthur W. Stillians, Chicago
Fred D. Weidman, Philadelphia

REFERENCE: J. A. M. A. 159:445-446 (Oct. 1) 1955.

The major changes in requirements for certification are

CHANGE IN INSTITUTIONAL STATUS

Add: (With change of directorship of dermatological training, reapplication for approval is necessary before the institution is appraised by the joint Residency Review Committee for Dermatology.)

PRECEPTORS

Add: Applications for preceptorship are submitted with the "Plan of Supervised Work" form. Approved preceptors, in conjunction with the director of training of the institution in which the candidate spends half his training time, submit an "Annual Graduate Training" form on each trainee. The preceptee files a "Preceptorship Evaluation" form following this training.

REFERENCE: J. A. M. A. 159:447-452 (Oct. 1) 1955.

There will be some changes in requirements for certification during the year 1956-1957. However, they are not available for inclusion at this time.

AMERICAN BOARD OF NEUROLOGICAL SURGERY

A. Earl Walker, Baltimore, Chairman
Edgar F. Fincher, Atlanta, Ga., Vice-Chairman
George S. Baker, Rochester, Minn.
E. Jefferson Browder, Brooklyn, New York
William V. Cone, Montreal, Canada
Dean Echols, New Orleans
Franc Ingraham, Boston
Edgar A. Kahn, Ann Arbor, Mich.
Frank Mayfield, Cincinnati
William T. Peyton, Minneapolis
John Raaf, Portland, Ore.
Leonard T. Furlow, Washington University Medical School, St. Louis, Secretary-Treasurer

REFERENCE: J. A. M. A. 159:452 (Oct. 1) 1955.

The major changes in requirements for certification are

SPECIAL TRAINING

Fourth sentence in the first paragraph changed to read: At least two years of this training must be had in one institution, and the board will not ordinarily approve periods of training in clinical neurological surgery of less than one year.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

F. Bayard Carter, Durham, N. C., President
Robert A. Kimbrough Jr., Philadelphia, Vice-President
Herbert E. Schmitz, Chicago, Vice-President
Walter T. Dannreuther, New York
Daniel G. Morton, Los Angeles
John L. Parks, Washington, D. C.
Conrad G. Collins, New Orleans
Robert L. Faulkner, 2105 Adelbert Rd., Cleveland 6, Secretary-Treasurer
Lawrence M. Randall, Rochester, Minn., Assistant Secretary

REFERENCE: J. A. M. A. 159:452-456 (Oct. 1) 1955.

For current requirements for certification, write to the Secretary of the American Board of Obstetrics and Gynecology.

AMERICAN BOARD OF OPHTHALMOLOGY

Brittain F. Payne, New York, Chairman
F. Bruce Fralick, Ann Arbor, Mich., Vice-Chairman
Merrill J. King, Rockland, Maine, Secretary-Treasurer
William L. Benedict, Rochester, Minn., Consultant
Conrad Berens, New York, Consultant
Frederick C. Cordes, San Francisco, Consultant
Georgiana D. Theobald, Oak Park, Ill., Consultant
Francis H. Adler, Philadelphia
James H. Allen, New Orleans
Walter S. Atkinson, Watertown, N. Y.
Alson E. Braley, Iowa City
Gordon M. Bruce, New York
Paul A. Chandler, Boston
Michael J. Hogan, San Francisco
John S. McGavic, Bryn Mawr, Pa.
Kenneth C. Swan, Portland, Ore.
Miss Lea M. Stelzer, Registrar, 56 Ivie Rd., Cape Cottage, Maine

REFERENCE: J. A. M. A. 159:457-459 (Oct. 1) 1955.

The major changes in requirements for certification are

PREREQUISITES

(Applicable to applicants who start residencies in ophthalmology after Dec. 31, 1956.)

Individuals who have completed three years of formal ophthalmological training (residency and basic science courses) may apply for the written qualifying test after completion of 12 months of practice or 12 months of institutional work, a total of 48 months. All other individuals (with less formal training) may apply for the written test after 60 months in ophthalmology or 72 months of combined ophthalmology and otolaryngology. A basic course is recognized as equivalent in time to residency training. All time requirements must be completed by the date of the written test.

GENERAL REQUIREMENTS FOR ALL CANDIDATES

Substitute following for No. 7:

7. Licensure in the state, province, or country where the candidate practices

FEES

For original written test, $100 payable with application.

For original clinical examination, $50 payable on successful completion of the written.

Repeating written test, $65.

Repeating clinical examination, $65.

Single conditions, $25.

Two or more conditions, $35.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY

Donald E. King, San Francisco, President
Willima M. Roberts, Gastonia, N. C., Vice-President
Clarence H. Heyman, Cleveland
Mather Cleveland, New York
Charles J. Frankel, Charlottesville, Va.
George J. Garceau, Indianapolis
Edwin F. Cave, Boston
William H. Bickel, Rochester, Minn.
Sam W. Banks, 116 S. Michigan Ave., Chicago 3, Secretary-Treasurer

Advisory Council to the Board

William T. Green, Boston
Hugh Smith, Memphis, Tenn.
Francis M. McKeever, Los Angeles
Harold A. Sofield, Oak Park, Ill.

REFERENCE: J. A. M. A. 159:459-461 (Oct. 1) 1955.

The major requirement changes for certification are

REQUIREMENTS OF PRECEPTORSHIP TRAINING

1. Candidates in preceptorship training, or possessing signed contracts prior to Jan. 1, 1957, will receive training credit for the entire period during which their contracts are in force. No new contracts will be accepted by the board for preceptorship training after Jan. 1, 1957.

4. Deleted: "If facilities and instruction in the related basic sciences are not available, the candidate must spend a minimum of six months as a student in an institution approved for basic science training in orthopaedic surgery."

5. Deleted: "The candidate must train as a full-time assistant to the preceptor and may not maintain a separate office or engage in individual practice."

MILITARY SERVICE

3. "Applicants who served in military hospitals not approved by the Council for resident orthopaedic training whose service is judged by the board to have been equal to that of approved resident orthopaedic training may be granted a maximum of one year of resident orthopaedic training."

4. No applicant may be granted more than one year of resident training credit for military service in installations not approved by the Council for resident orthopaedic training.

AMERICAN BOARD OF OTOLARYNGOLOGY

Officers

Gordon D. Hoople, Syracuse, N. Y., President
Bernard J. McMahon, St. Louis, Vice-President
Dean M. Lierle, University Hospitals, Iowa City, Secretary-Treasurer

Senior Counselors

George M. Coates, Philadelphia
Ralph A. Fenton, Portland, Ore.
Gordon F. Harkness, Davenport, Iowa
H. I. Lillie, Rochester, Minn.
Carl H. McCaskey, Indianapolis
Henry B. Orton, Newark, N. J.
Ernest M. Seydell, Wichita, Kan.
Frank R. Spencer, Boulder, Colo.
Fletcher D. Woodward, Charlottesville, Va.

Board of Directors

Lawrence R. Boies, Minneapolis
Louis H. Clerf, Philadelphia
Daniel S. Cunning, New York
Russell M. Decker, Pasadena, Calif.

Lewis F. Morrison, San Francisco
Werner Mueller, Boston
C. Stewart Nash, Rochester, N. Y.
Arthur W. Proetz, St. Louis
LeRoy A. Schall, Boston
Harry P. Schenck, Philadelphia
O. E. Van Alyea, Chicago

Assistants

George F. Reed, Boston
William C. Huffman, Iowa City
Clair M. Kos, Iowa City
James A. Moore, New York
Walter P. Work, San Francisco

reference: J. A. M. A. 159:462-463 (Oct. 1) 1955.

The major changes in requirements for certification are

GENERAL REQUIREMENTS

The following requirement is deleted: 1. A candidate must be a citizen of the United States or the Dominion of Canada.

REEXAMINATION

Candidates who have failed in the examination may be accepted for reexamination upon recommendation of the Credentials Committee. Satisfactory evidence of further study and progress will be required. A new application must be filed. The fee for reexamination for such candidate is $150.

AMERICAN BOARD OF PATHOLOGY

Shields Warren, Boston, President
William B. Wartman, Chicago, Vice-President
Roger D. Baker, Durham, N. C.
Israel Davidsohn, Chicago
A. S. Giordano, South Bend, Ind.
James W. Kernohan, Rochester, Minn.
Douglas MacFadyen, Chicago
James B. McNaught, Denver
James N. Patterson, Tampa, Fla.
S. Brandt Rose, Philadelphia
John R. Schenken, Omaha
Edward B. Smith, *Secretary-Treasurer, Indiana University* Medical Center, 1040-1232 W. Michigan St., Indianapolis

reference: J. A. M. A. 159:463-467 (Oct. 1) 1955.

The major changes in requirements for certification are

APPLICATION BLANK AND FEE

Paragraph 2: The application or examination fee for candidates is $100. If the candidate fails in his examination he will be admitted to a second examination after one year. The applicant must pay an additional fee of $50 before a second examination will be given.

Paragraph 3: The application fee of $100 has been determined after careful consideration and is based on actual estimates of the expenses of examination and administration. None of the Board members receive any compensation for their services except actual expenses incurred.

AMERICAN BOARD OF PEDIATRICS

Lee F. Hill, Des Moines, Iowa, President
A. Ashley Weech, Cincinnati, Vice-President
Ralph V. Platou, New Orleans, Secretary-Treasurer
James Marvin Baty, Boston
John A. Bigler, Chicago
James G. Hughes, Memphis, Tenn.
Joseph A. Johnston, Detroit
Robert B. Lawson, Miami, Fla.

SPECIAL REQUIREMENTS IN PUBLIC HEALTH

1. Successful completion (after internship) of at least one academic year of graduate study leading to the degree of Master of Public Health or an equivalent degree or diploma; or training or study deemed by the board to be substantially equivalent to such graduate study.

2. Residency (after internship) of at least two years of field experience in general public health practice, which included planned instruction, observation, and active participation in a comprehensive, organized public health program, one year of which may be an approved clinical residency in a field directly related to public health.

3. A period (after internship) of not less than three years, in addition to 1 and 2 above, of special training in or teaching or practice of public health.

4. Limitation of practice to full-time teaching or practice of public health as a specialty.

The major change in requirements for certification is

Delete section under "Certification in Occupational Medicine Without Examination (the Founders Group)."

AMERICAN BOARD OF PROCTOLOGY

Robert A. Scarborough, San Francisco, President
Harry E. Bacon, Philadelphia, President-Elect
Garnet W. Ault, Washington, D. C., Vice-President
Frederick B. Campbell, Kansas City, Mo.
Walter A. Fansler, Minneapolis
A. W. Martin Marino, Brooklyn, N. Y.
Louis E. Moon, Omaha
Hyrum R. Reichman, Salt Lake City
Robert J. Rowe, Dallas, Texas
Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y., Secretary

Advisory Council

Louis A. Buie, Rochester, Minn.
Louis J. Hirschman, Traverse City, Mich.
Curtice Rosser, Dallas, Texas
George H. Thiele, Kansas City, Mo.

REFERENCE: J. A. M. A. 159:475-476 (Oct. 1) 1955.

The major changes in requirements for certification are

Special Professional Qualifications.—They shall have completed:

2. Three years of approved general surgical residency and one year of approved proctologic residency by special arrangement with the board; or

3. Three years of approved general surgical residency and two years of approved proctologic preceptceship by special arrangements with the board; or

4. Two years of approved general surgical residency and three years of approved proctologic preceptceship.

EXAMINATIONS

Seventy-five per cent is the passing grade on all examinations. Examination papers are identified only by numbers and the examiners do not know the identity of the examinees.

Part 1.—This consists of a comprehensive written examination in the basic sciences, including anatomy, physiology, pathology, bacteriology, and biochemistry. The examination is held in the fall of the year simultaneously in several cities of the United States. Upon approval of the American Board of Proctology, candidates who have passed part 1 of the examinations of the American Board of Surgery and who have completed required training in proctology may not be required to take part 1 of the examinations of the American Board of Proctology.

Part 2.—This is a practical examination that is held in the community in which the candidate conducts his professional activities. (It may be omitted at the discretion of the board, in which case the candidate will be notified by the secretary.) It is endeavored to arrange the examination at a time suitable to both the candidate and the examiner. The examination includes inspection of: 1. surgical operations, 2. hospital rounds, 3. hospital and office records, 4. office practice.

Part 3.—This consists of comprehensive written and oral examinations on the theory and practice of proctology, and includes roentgenologic interpretation. The examination is usually held in the fall of the year in one designated city of the United States. The candidate is not admitted to part 3 of the examinations until he has completed the requirements of part 2. The oral portion of the examination is conducted by members of the board or its designated examiners. An attempt is made to ascertain the candidate's knowledge of current proctologic literature, his knowledge of the basic sciences, and the extent of his clinical experience and other qualifications.

REEXAMINATION

A candidate who fails may be reexamined after one year has elapsed. The act of filing an application for reexamination is the candidate's responsibility. Candidates who have failed a reexamination may petition the board for another examination after two years have elapsed. Acceptable evidence of additional preparation shall be submitted with this petition.

FEES AND DUES

Fees.—Application fee. A fee of $25 shall accompany the application.

Examination fee. A fee of $150 is due and payable when the candidate is notified that he has been approved for examination

Reexamination fee. A fee of $50 is due and payable when the candidate is notified that he has been approved for reexamination.

Reexamination in Part 2.—Candidates for reexamination in part 2 may be held responsible for payment of expenses incurred by the board in conducting the reexamination. No fee shall be returned to the candidate without board approval. All fees shall be made payable to the American Board of Proctology and shall be sent to the secretary.

Dues.—Each diplomate is required to pay annual dues in the amount of $10 to the board for a period of 10 years following certification. Fees and dues are utilized to defray expenses incurred by board activities.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY

Frederick P. Moersch, Rochester, Minn., President
George N. Raines, Washington, D. C., Vice-President
Harvey Bartle Jr., Philadelphia
C. H. Hardin Branch, Salt Lake City
Henry W. Brosin, Pittsburgh
Russell N. DeJong, Ann Arbor, Mich.
Knox H. Finley, San Francisco
Francis M. Forster, Washington, D. C.
Francis J. Gerty, Chicago
William Malamud, Boston
Paul I. Yakovlev, Boston
David A. Boyd Jr., Secretary-Treasurer, 102-110 Second Ave., S.W., Rochester, Minn.

REFERENCE: J. A. M. A. 159:476-478 (Oct. 1) 1955.

The major changes in requirements for certification are Specialized Training: All applicants who wish to qualify for examination for certification in psychiatry or neurology under the regulations relating to training credit and who began training on or after July 1, 1956, must show that at least 24 months of their residency training have been secured in residency training programs approved for at least two years of residency training in the specialty in which they seek certification.

TRAINING IN THE ARMED FORCES

Delete first paragraph.

PAYMENT OF FEES

The candidate upon filing his application shall accompany it with an application fee of $50, which is not returnable. If a preliminary written examination has been decreed, an additional $25 fee will be required at the time of the applicant's acceptance When notified by the secretary that he is accepted for the oral and practical examination, the candidate shall send to the secretary an examination fee of $75. A candidate who has been certified in either psychiatry or neurology and who has been admitted to supplementary examination for the other certificate shall pay an additional examination fee of $75.

A candidate who has failed in one examination is eligible for reexamination within one year upon payment of a reexamination fee of $75. After the year has elapsed, he must submit a new application and pay new application and examination fees. If he fails the reexamination, he may, after two years have elapsed, submit a new application and $50 fee, present evidence of further training, and pay an examination fee of $75.

A candidate who fails in one or two subjects is eligible for reexamination in those subjects within one year upon payment of a reexamination fee of $50. After the year has elapsed he must submit a new application and pay new application and examination fees and repeat the entire examination. If he fails the reexamination, he may apply again for the complete examination after two years upon submission of evidence of further training and upon payment of an application fee of $50. If admitted to the examination, he must pay a new examination fee of $75.

Any candidate who finds himself unable to attend an examination to which he has been admitted and does not notify the secretary at least three months before the date of the examination will forfeit his examination fee. Any candidate who fails to appear for examination within a period of three (3) years following the date of notification of eligibility for examination shall be required to submit a new application and pay the attendant fee. If a candidate dies before his certificate is issued, all fees will be returned to his estate.

References: J. A. M. A. 159:478-479 (Oct. 1) 1955.

The major changes in requirements for certification are

CERTIFICATES

Change the second paragraph to read: 2. A certificate to the effect that the applicant has been found qualified to practice radiology in one or more of the following special fields: (*a*) diagnostic roentgenology (*b*) therapeutic radiology.

Substitute: 3. Certification in Nuclear Medicine. Certification in the handling and uses of radioactive isotopes is now offered to those candidates applying in Radiology or Therapeutic Radiology. After June 30, 1957, all candidates for Radiology or Therapeutic Radiology will be urged to seek certification in this field. As of June 30, 1960, it will be mandatory. A suitable medallion will be issued to those certified in Nuclear Medicine until June 30, 1960, after which date the certificate in Radiology or Therapeutic Radiology will include Nuclear Medicine.

DEFINITIONS

Delete: 2. Roentgenology is that branch of radiology that deals with diagnostic and therapeutic application of roentgen rays.

AMERICAN BOARD OF SURGERY

The major changes in requirements for certification are

Under group 1 there is a change in regard to candidates who complete only four years of a hospital residency program that is for a period longer than four years. It now reads: "If the hospital residency training is for a longer period than four years the candidate who completes only four years and does not assume the responsibilities of a senior year cannot be considered in the group 1 category. Such a candidate must complete a senior year in a hospital approved for four years or submit his qualifications to the examination committee of the board for their decision concerning further training requirements."

Also under group 2 it is stated: "Credit will not be granted for separate periods of time devoted exclusively to research or a preclinical discipline, although the day-to-day integration of these disciplines with clinical surgery is highly desirable. The program must have included three years of clinical surgery and the final year must have been spent in the capacity of senior or chief resident in general surgery."

THE STUDENT AMERICAN MEDICAL ASSOCIATION LOOKS AT INTERNSHIPS

During the course of the past year, the Student American Medical Association conducted a survey of interns with respect to the question: "Is the Intern Year Worthwhile—or Should It Be Abolished?" An analysis of a 41% return on an internship evaluation questionnaire sent to 1,450 interns representing a geographical cross section of the United States was presented at the annual meeting of the Student American Medical Association held in Chicago last May. Eighty-five per cent of the respondents were in rotating internships, 8% in straight, and 4% in mixed. This distribution according to type of internship correlates fairly well with the 89% rotating, 10% straight, and 1% mixed service representing the total of 11,616 approved internships offered last year. While the interpretation of a sampling of any group on matters of interest and concern to the group must be made with care and in its proper perspective, this particular questionnaire highlighted certain points of interest to all concerned with this phase of medical education.

Over 90% of those replying to the questionnaire felt that the internship year should be continued; while a small number suggested that a fifth year of medical school might advantageously replace it. The vast majority of the interns indicated that they did not believe the internship program in their institution was being handled with the primary purpose of teaching and that few hospitals, private or public, are offering internships designed to give adequate preparation for general practice. Private hospitals showed a much smaller percentage of satisfied interns and in this study were graded as offering poorer internships as compared to the teaching and large municipal institutions. In general, the amount of publicity a hospital receives often appeared to be in inverse proportion to the quality of the internship offered.

A large majority of the questionnaire responses indicated that the interns felt they were receiving less than the minimum time desirable under the supervision or instruction of full-time staff personnel. About two-thirds of the group felt that they were allowed adequate responsibility to gain over-all medical experience but that their total responsibilities were in excess of the degree of supervision and teaching offered to them. About 3% of the respondents felt that the intern year they were experiencing was a "farce and a waste of time" because they were doing essentially nonprofessional "scut-work."

The concern of interns over the financial problems associated with this phase of education beyond medical school was reflected in numerous ways through the questionnaire responses. For instance, over 95% of the returns from those in military internships reported favorably. Although these individuals indicated some restrictions in the type of training offered, this was offset by their freedom from financial worry, since they received the highest intern stipends. There was an almost unanimous expression to the effect that the intern pay scale is inadequate with respect to the benefits their services offer to the institutions in which they work and which they feel are not adequately counterbalanced by the educational experiences gained.

In this current report on internships and residencies it will be noted that there has been an increased recognition of the financial problems encountered during the intern year and that in recent years most hospitals have materially augmented intern stipends. Medical students recognize the importance of sound internship experiences and where finances permit will still select the internships in an institution where the teaching and supervision are known to be outstanding, even though stipends may be minimal. In recent years, many social and economic readjustments have taken place in the setting of medical education. Large numbers of medical students are married today and may have families at the time they begin internship. Many of them are already under financial burdens undertaken to complete their medical school courses and in seeking their required graduate education find it necessary to give undue weight to stipends accompanying internship appointments. This essentially means that it has become possible, in some instances, for institutions to compete for interns through the medium of attractive stipends rather than placing primary emphasis on the educational opportunity and experience that they have to offer. This could be at least partially offset if all hospitals conducting approved internships offered basic stipends in keeping with the changing economic scene.

However, in the long run, it is the experience of the intern in obtaining the supervised graduate educational experience he needs that will determine whether an institution continues to attract intern staff personnel, regardless of the remuneration it may offer. The oncoming senior medical students have their "ears to the ground," just as did those of us who graduated many years ago, and learn from their friends who are interning whether the hospital administration and staff are concerned with internships solely from the standpoint of service or whether education and service are properly balanced. As the years roll by and service needs increase, some responsible staff members seem to forget this simple fact and fail to heed it or to adequately interpret it to hospital administrators. The question as to whether internships are worthwhile becomes a direct challenge to the professional staff and administration of every hospital accepting medical school graduates for such experiences.

PROGRESS TOWARD "FULL TRAINING" REQUIREMENTS FOR RESIDENCY APPROVAL

Increasingly in recent years, attention and thought have been given to full training requirements by physicians who develop and direct residency programs in hospitals and by the examining boards in the medical specialties, colleges, and the Council, which participate in residency approvals (THE JOURNAL, September 24, 1955, page 378). Thought has been centered on how a resident upon entering a training period of several years' duration can be assured of continuity in supervision and increasing, graded responsibility. As a result of these considerations, residency review committees in several specialties have adopted policies intended to encourage educational continuity.

The same principle is applicable in all of these policies; namely, that hospitals, to qualify for continued approval, are required to provide "full training" in the specialty, either independently or in collaboration with other hospitals through integration of their programs. Approval for residency training in anesthesiology, general surgery, otolaryngology, and plastic surgery, as well as in medical subspecialties, allergy, cardiovascular diseases, gastroenterology, and pulmonary diseases has for some time been limited to hospitals offering full training, either independently or in collaboration with other hospitals. Announcement of adoption of this policy relating to residency programs in pediatrics appeared in THE JOURNAL, April 10, 1954, page 1303. Similar statements relating to residency programs in orthopedic surgery, radiology, and urology were published in THE JOURNAL, September 24, 1955, pages 382 and 383. In this issue (page 430) there is an announcement on the future policy relative to approval of residency training in ophthalmology. These policies, which have been adopted to preclude the possibility of a resident taking his training in two or three isolated programs with no assurance of continuity of supervised experience or progression of responsibility, are considered educationally sound.

ANNUAL REPORT ON INTERNSHIPS AND RESIDENCIES

The 30th Annual Report on Internships and Residencies published in this issue of THE JOURNAL presents a compilation of statistical data and information on graduate training programs for the past year and listings of hospitals approved by the Council on Medical Education and Hospitals for the training of interns and residents for the year beginning July 1, 1957. The report is based on information furnished by each hospital approved for the training of interns and/or residents in specialties and includes an analysis of the statistical tables regarding these phases of medical education.

As has been the case for several years, there was a slight increase in the number of hospitals approved for intern training and in the number of intern positions available. As of September 1, 1955, 867 hospitals were approved for 11,616 internships. Eighty-three per cent of the available positions were filled. The distribution of internships by type remained stable: rotating 89%, straight 10%, and mixed 1%. There was an appreciable increase in the stipend for interns during the year; the average cash stipend paid by affiliated hospitals was $121 per month; that paid by nonaffiliated hospitals was $169 per month.

There has been an increase of 1,030 residency positions during the year to 26,516. The occupancy rate on September 1, 1955, increased from 80% (1954) to 81%. The increased occupancy rate for both internships and residencies is attributed to the fact that there are in excess of 6,000 foreign medical school graduates serving in these positions. Resident training programs are approved in 30 fields of medicine and surgery. In 1955, there were 31,028 interns and residents on duty in approved hospitals—one out of seven physicians in this country is taking graduate medical training.

On September 1, 1955, a total of 6,123 intern and resident training programs were sponsored by 1,373 hospitals. Of this total number of hospitals, 171 were approved for intern training only; 506 were approved for the training of residents only; and 696 were approved for the training of both interns and residents.

The report includes a brief explanation of the National Intern Matching Program and the results of its 1956 operations; an explanation of the changes made in the revised "Essentials of an Approved Internship," including an interpretation of the "one-fourth rule"; information concerning the internship and the residency review committees; the plan for evaluation of foreign medical school graduates, as developed by the cooperating committee; and a statement regarding the Sears-Roebuck Foundation.

It is the sincere hope of the Council that this report will be helpful to medical students, recent medical school graduates, medical educators, and all others who are interested in medical education at the internship and residency levels.

EXPENDITURES FOR HOSPITALS AND PHYSICIANS

For the first time, the annual personal consumption expenditures of the American people for hospital services exceeded those for physicians' services. According to the July, 1956, issue of the *Survey of Current Business*,[1] personal consumption expenditures for hospital services during 1955 were 3,130 million dollars as compared with 3,070 million for physician services. Although the difference in the two amounts is not very great and both are subject to subsequent revision, these data mark 1955 as a turning point in the history of medical economics. In 1929 the estimates by the Department of Commerce of personal consumption expenditures were 959 million dollars for physician services and 403 million for hospital services; in the period 1935-1939 the average annual amounts were 821 million and 448 million; they rose to 2,435 million and 1,975 million in 1950. In other words, the physicians' share of "the medical care dollar" declined from 33 cents in 1929 to 27.2 in 1955, whereas the hospitals' share rose from 14 to 27.8 cents. Those who are disturbed about the increases in the outlays for medical care, while praising its high quality, should realize that personal consumption expenditures for the services of physicians are no longer the largest in the American family budget for medical care. Although these data, by definition, exclude expenditures by all units of government for medical care, it can now be stated that the hospital has attained its majority in the realm of medical economics. More persons are hospital patients and more babies are born in hospitals; and the range of hospital services has expanded. Without the great growth of hospital services, the rapid health progress of the past several decades could not have been achieved.

---

[1] National Income and Product of the United States 1955, Surv. Current Business 36: 21 (July) 1956.

[2] Expenditures for Hospitals and Physicians, publication M-106, Bureau of Medical Economic Research, American Medical Association, Chicago, 1956.

Another reason for the ascendency of personal consumption expenditures for hospital services is the more rapid rise in hospital prices than in physician fees. According to the Consumer Price Index and its many subindexes published by the United States Bureau of Labor Statistics, physicians' fees in 1955 were 65.8% above the 1935-1939 level as compared with increases of 237.7% in the index of hospital room rates and 91.4% in the over-all Consumer Price Index. In obtaining personnel and supplies the hospital has practically no protection against the forces of inflation; these forces, combined with the ever-increasing demand for hospital services, account for the extremely rapid rise in hospital room rates.[2]

IDENTIFICATION OF THE NEWBORN INFANT

Mix-ups involving two or more babies are quite rare in hospital nurseries, but they still can happen. In one state alone in a period of 18 months eight mix-ups or alleged mix-ups occurred. When such a mix-up, alleged or actual, does occur, a torrent of unfavorable publicity is unloosed and the parents concerned may be haunted by a lifetime doubt about their child. The confusion sometimes arises because two mothers in a hospital at the same time have the same surname; it sometimes arises because a single identification becomes detached from the baby; or it may even arise because parents get to wondering after they leave the hospital how the attendants maintained the identity of the babies. Sometimes the confusion is easily straightened out, and sometimes it leads to giving the wrong baby a harmless prescription; only rarely does it lead to an actual exchange of babies. The American Hospital Association has long been aware of this problem, and, because it has been found that photographs, footprints, handprints, and fingerprints are adjuncts but cannot yet be considered reliable as the sole means of identifying the newborn infant, the association has urged the adoption of a standard operating procedure that if applied would reduce mix-ups to the vanishing point.

The main features of this procedure are as follows: 1. Each baby should be marked in the delivery room with two items of identification. 2. The identification items should show the mother's full name, date and time of birth, and some correlation with the mother, such as her fingerprint or number. 3. Each time the baby comes to the mother, the mother should be informed that it is her responsibility to identify her baby by the marking. 4. When the baby and mother are discharged, one of the bands should be removed, preferably by the mother, and, after the mother has properly identified her baby, the removed identification should then be pasted to the baby's chart. The mother should acknowledge in writing that this is how her baby was marked and that she identified it as hers. The leaflet that gives the full procedure in detail has been available since December, 1949. Once established as a routine, this procedure, far from being a burden, would prevent a type of mistake that would otherwise be easy to make but that is nonetheless inexcusable.

MUNICIPAL SWIMMING POOLS

It is generally felt that the healthful benefits derived from a properly constructed and operated municipal swimming pool far outweigh the possible hazards. Our disgraceful record of accidents as the leading cause of death among the youth of our country obligates our communities to teach our children to swim and play safely; drownings number in the thousands annually. A supervised program at a municipal pool can do its part during the vacation periods of the year. Possible health and disease hazards are minimal where preventive measures are incorporated into the design and operation of the pool. The question of overemphasis on high diving is a real one. It should always be kept in mind that the primary purpose of the pool is for teaching children to swim and gain healthful exercise in the sun and fresh air.

According to the joint committee on swimming pools and bathing places of the American Public Health Association, about 300 sq. ft. of pool surface (10-ft. diameter) should be reserved for each diving board or platform. No platform or board at a public pool should be higher than 10 ft. above the water level. For a diving board elevated 9 or 10 ft. above the water, it is recommended that the minimum depth of the pool be 10 ft.

The types of accidents associated with high diving in properly designed pools are largely slips and falls on the board or platform and diving on top of swimmers below. These may be brought to a minimum by proper construction and supervision. Touching the bottom with any force seldom occurs in pools conforming to minimum depth requirements. A faultily executed dive from a high board may be expected to result in minor sprains and bruises. It is felt by some that excessive diving may lead to nasal and aural involvements, and the use of protective caps over ears or rubber plugs and nose clips is recommended.

ORGANIZATION SECTION

A. M. A. CLINICAL SESSION IN SEATTLE

An outstanding scientific program and excellent hotel accommodations await the nation's physicians at the A. M. A. Clinical Session in Seattle Nov. 27-30. In cooperation with the Council on Scientific Assembly, the general committee, headed by Chairman M. Shelby Jared of Seattle, has been working diligently for months and reports that plans are near completion. The center of activities will be Seattle's Civic Auditorium, where scientific sessions will be held and exhibits will be displayed. Conveniently located, the auditorium is easily accessible from downtown hotels, and transportation will be available for commuting to and from the meetings. A cafeteria will be operated in the auditorium for midday meals. The headquarters for the Clinical Session will be the Olympic Hotel, where House of Delegates sessions and meetings of the Board of Trustees, councils, and reference committees will be held.

The scientific program will be beamed at the general practitioner, and subjects have been carefully chosen to be of interest and practical value. The program will include panel discussions, individual papers, motion pictures, and closed-circuit television clinics. The panel discussions will cover such subjects as hypertension, hemolytic anemia, prenatal care, problems of aging, epilepsy, low back pain, liver disease, and vascular disorders. Twenty topics will be considered by panels of men prominent on the national scene and in the Northwest.

There will be 45 papers, considering fluid balances, urologic problems, office psychiatry, varicose veins, fractures, diabetes, heart disease, and many other subjects. Well-known medical educators and practicing physicians from all parts of the United States will participate. The television clinics will include both wet (operative) and dry (nonoperative) clinics. Talent will be drawn largely from Seattle because of the necessity of rehearsals and frequent briefing. There will be clinics on block anesthesia, treatment of burns, bleeding problems, intestinal obstruction, cesarean section, hand surgery, hysterectomy, vein stripping, and other subjects. The program for the medical motion pictures and schedule of papers, panels, and television shows will be published soon in The Journal. Scientific and technical exhibits have been arranged through the A. M. A. headquarters. They promise to be as interesting and varied as in the past.

Elaborate plans are being made for a banquet and entertainment for the House of Delegates, Board of Trustees, A. M. A. officials, and their wives, Wednesday evening, Nov. 28, in the headquarters hotel. Prepaid medical service plans of Washington, Oregon, and Idaho are planning to conduct a hospitality suite in grandiose style for three days during the session. The prepaid plans of these states will present an exhibit of their services to the public in connection with the hospitality suite. Plans also are near completion for Auxiliary activities during the Clinical Session. Sightseeing tours and other events are on the agenda. Physicians are urged to make their reservations early. A reservation form will be found in The Journal.

QUARTERLY CUMULATIVE INDEX MEDICUS

Volume 55 of the Quarterly Cumulative Index Medicus, covering literature for the first half of 1954, has been mailed to subscribers and is now available for purchase from the Order Department of the American Medical Association. Preparation of Volume 56 (July-December, 1954) is under way, and this issue should be in print early in 1957.

CHARLES KETTERING RECEIVES CITATION

The American Medical Association presented a citation to Charles F. Kettering on his 80th birthday Aug. 29 for "his lifelong enthusiasm and ingenuity in charting new courses in medical research." The citation was presented to the retired vice-president of General Motors Corporation at a luncheon at the Country Club in Dayton, Ohio. As director of the Sloan-Kettering Institute for Cancer Research and as chairman of the Charles F. Kettering Foundation, Mr. Kettering has provided the opportunity for advanced study in the natural sciences, nutrition, cancer, and air pollution.

Dr. Tom D. Spies, scientific director of the nutrition clinic of the Hillman Hospital, Birmingham, Ala., presented the citation, which reads: "The American Medical Association extends its best wishes to Charles F. Kettering on the occasion of his eightieth birthday, and presents this citation as a token of its appreciation for his selfless dedication, through science, to the well-being of the American people. Charles Kettering's lifelong enthusiasm and ingenuity in charting new courses in medical research have brought about important advances in the study of cancer, industrial health, and the natural sciences. To this philanthropic man of science, the members of the American Medical Association extend a heartfelt 'thank you.'" The citation bears the signatures of the A. M. A. President, Dr. Dwight H. Murray, and Dr. Gunnar Gundersen, Chairman of the A. M. A. Board of Trustees.

MEDICAL NEWS

CALIFORNIA

Postgraduate Clinics.—The University of California Extension and the division of postgraduate medical education at the University of California at Los Angeles is initiating a course on U. C. L. A. teaching clinics, to be held from 5:30 to 7 p. m. on the first and third Thursday of the month from Oct. 4 through June 20, 1957. Most of the programs, to be presented at the Medical Center, will use case material currently on its wards. The Bay District Branch of the Los Angeles County Medical Association will serve as the sponsoring agency for the program, which will be available to their own branch members as well as members of the Los Angeles County and California Medical associations. A detailed folder is available without charge on request to Dr. Thomas H. Sternberg at the University of California Medical Center, Los Angeles 24.

Mental Health Programs.—The University Extension and the School of Nursing at the University of California at Los Angeles will sponsor an all-day institute on community mental health programs Sept. 29 in the Chemistry Building. Dr. Paul V. Lemkau, commissioner of the New York City Community Mental Health Board, will speak on "How a Community Can Develop Effective Mental Health Programs." A late morning session will include a panel discussion, with invited speakers including Dr. Frank F. Tallman, head of the division of preventive psychiatry, University of California at Los Angeles School of Medicine, and Dr. Arnold D. Schwartz, director, mental health division, California State Department of Public Health. Dr. Portia Bell Hume, Berkeley, deputy director of community service, California State Department of Mental Health, and Dr. Lemkau will summarize the conference results at the afternoon session. Registration fee for the campus conference is $3.

CONNECTICUT

Anesthesia Seminar.—Beginning on Sept. 25, a seminar, "The Pharmacological Background to Anesthesia," will be offered by the department of anesthesia of the Hartford Hospital, with members of the department of pharmacology, Yale University School of Medicine, participating, on Tuesdays and Thursdays, 3 to 4:30 p. m. at the Hartford Hospital Amphitheater. The course, which covers respiration, the autonomic nervous system, body fluids, narcosis, sedatives, and hypnotics, analgesic and analeptic compounds, convulsants and anticonvulsants, volatile and gaseous anesthetics, local anesthetics, and relaxants, is designed primarily for those in anesthesia residency training but is open to interested practicing physicians. There is no fee for the seminar.

NEW YORK

Harrington Lecture.—The University of Buffalo School of Medicine announces that the Harrington Lecture, "The Metabolism of Normal and Malignant Human Cells in Tissue Culture," will be presented in Capen Hall Oct. 4, 4:30 to 5:30 p. m., by Dr. Harry Eagle, of the National Institute of Allergy and Infectious Diseases, Bethesda, Md.

Graduate Fortnight.—The 29th annual Graduate Fortnight of the New York Academy of Medicine will be presented Oct. 15-26. On Monday evening the following lectures will be given on "The Place of Hypophysectomy and Adrenalectomy in the Management of Neoplastic and Metabolic Diseases":

Hypophysectomy in Man, Rolf Luft, Karolinska Institute, Stockholm, Sweden.
The Place of Hypophysectomy and Adrenalectomy in the Complications of Diabetes, Laurance W. Kinsell, Institute for Metabolic Research, Oakland, Calif.
The Place of Adrenalectomy in the Management of Severe Hypertension, Charles C. Wolferth, University of Pennsylvania School of Medicine, Philadelphia.

During the first week the afternoon panel meeting, "The Management of Disseminated Neoplastic Diseases," will be moderated by Dr. David A. Karnofsky, Memorial Center for Cancer and Allied Diseases, New York City, and the Thursday afternoon clinical-pathological conference on hypertension by Dr. Alfred A. Angrist, Albert Einstein College of Medicine, New York City. On Wednesday evening "New Drug Therapy in Psychiatry and Hypertension" will be considered in the following presentations:

The Nature of Drugs with Mental Actions and Their Relation to Cerebral Function, Harry H. Pennes, Eastern Pennsylvania Psychiatric Institute, Philadelphia.
New Drug Therapy in Psychiatry: Clinical Uses and Abuses in Mental Disorders, Paul H. Hoch, Albany, N. Y., commissioner of mental hygiene, New York State.
A Clinical Evaluation of Hypotensive Agents, Irvine H. Page, Cleveland Clinic, Cleveland.

Friday evening the general topic "An Evaluation of the Present Status of Cardiac Surgery" will be developed in "Physiological Considerations and Clinical Indications for Cardiac Surgery" by Dr. Howard B. Burchell, Mayo Clinic, Rochester, Minn.; "Surgery of Congenital Heart Disease" by Dr. Robert E. Gross, Children's Medical Center, Boston; and "Surgery of Acquired Heart Disease" by Dr. Frank Glenn, New York Hospital–Cornell Medical Center. The second week will offer a Monday afternoon panel meeting, "Surgical Management of Cardiovascular Disease," with Dr. Ludwig W. Eichna, New York University–Bellevue Medical Center, as moderator, and a Friday afternoon panel on "Therapy of Infections" moderated by Dr. David E. Rogers of the New York Hospital–Cornel Medical Center. "The Adrenal Cortical Steroids and Their Analogues" will be discussed Tuesday evening in the following program:

Biosynthesis of Adrenal Cortical Hormones, Gregory G. Pincus, Sc.D., Worcester Foundation for Experimental Biology, Shrewsbury, Mass.
Role of the Adrenal Cortical Steroids and Their Analogues in Electrolyte and Fluid Metabolism, Louis J. Soffer, Mount Sinai Hospital, New York City.
Clinical Uses and Hazards of the Adrenal Hormones and Their Analogues in the Management of Rheumatic Diseases, Joseph J. Bunim, National Institute of Arthritis and Metabolic Diseases, Bethesda, Md.

Dr. John G. Kidd, New York Hospital–Cornell Medical Center, New York City, will serve as moderator for the Wednesday afternoon clinical-pathological conference, "An Endocrine Problem." Thursday evening will be devoted to consideration of poliomyelitis. "The Nature of Viruses" will be presented by Mark H. Adams, Ph.D., New York University–Bellevue Medical Center, New York City; "Present Status of Attenuated Live Virus Poliomyelitis Vaccine" by Dr. Albert B. Sabin, Children's Hospital Research Foundation, Cincinnati; and "Recent Experience and Present Status of Killed Virus Poliomyelitis Vaccine" by Dr. Joseph E. Smadel, National Institutes of Health, Bethesda, Md. There will be a registration fee of $10 for nonfellows of the academy. Medical officers of the armed services, in uniform, will be admitted without charge. Interns and residents will be admitted without charge, provided they present letters from their chiefs of service. All inquiries should be addressed to: Secretary, Graduate Fortnight, New York Academy of Medicine, 2 E. 103rd St., New York 29.

OHIO

Course on Pediatric Practice.—The Frank E. Bunts Educational Institute, affiliated with the Cleveland Clinic Foundation, will present the fourth annual postgraduate continuation course in pediatrics, "Current Therapy in Pediatric Practice," Sept. 26-27 at the institute, 2020 E. 93rd St., Cleveland 6. Out-of-state guest speakers will include Drs. Lawrence K. Pickett, associate professor of surgery, State University of New York College of Medicine at Syracuse, N. Y., and James L. Wilson, professor of pediatrics and communicable diseases, University of Michigan Medical School, Ann Arbor, Mich. A symposium on the management of acute gastroenteritis in pediatric practice has been scheduled for 4:20 p. m. on Wednesday and a symposium on trauma for the same time on Thursday.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

PENNSYLVANIA

Phi Delta Epsilon Lectureship.—The Nu chapter of the Phi Delta Epsilon fraternity at the *University of Pittsburgh School of Medicine* will hold its 11th annual lectureship Oct. 4 at 4:30 p. m. in the new medical school auditorium. The guest speaker, Dr. George Crile Jr., chairman of the department of surgery, Cleveland Clinic, will discuss "Physiologic Versus Anatomic Approach to the Problem of Goiter."

Philadelphia

Rehabilitation Course.—The University of Pennsylvania announces that the favorable response to the initial presentations of the course "Principles of Rehabilitation" has resulted in future scheduling for the following dates: Oct. 8-12, and Dec. 10-14, 1956; Feb. 4-8, April 22-26, and June 17-21, 1957. The course, designed to present the basic concepts of rehabilitation in all its aspects, is open to physicians, registered nurses, occupational therapists, social workers, rehabilitation counselors, and others concerned with rehabilitation of the handicapped. Principles and methods are presented through lectures, clinical demonstrations, and group discussions. The instructional staff includes representatives from the various divisions of the University of Pennsylvania and guest lecturers. Provisions for granting a limited number of trainee stipends to eligible persons attending the course have been made by the U. S. Office of Vocational Rehabilitation. Requests for detailed information may be addressed to the Rehabilitation Center, Hospital of the University of Pennsylvania, Philadelphia 4.

TENNESSEE

Postgraduate Courses.—The University of Tennessee College of Medicine, Memphis, announces the following postgraduate courses: Obstetrics and Gynecology, Oct. 3-5; Clinical Electrocardiography, Oct. 17-19; Radiology, Nov. 14-16; Psychiatric Problems in General Practice, Jan. 16-18, 1957; Office Urology, Feb. 27-March 1; Pediatrics, March 27-29; Fractures and Dislocations, April 24-26; Selected Problems in Internal Medicine, May 22-24; and Surgical Management of Acute Injuries, July 24-26. In addition, five-day diversified courses will be offered by the divisions of pediatrics (Jan. 21-25) and radiology (March 11-15), with enrollment limited to four physicians. The programs will include ward rounds with the staff, discussion of cases, attendance at clinical conferences, and work in the outpatient department. Further information may be obtained from the Postgraduate Department, 62 S. Dunlap St., Memphis.

WEST VIRGINIA

Rural Health Conference.—Dr. Franklin S. Crockett, West Lafayette, Ind., and Mr. Aubrey D. Gates, Little Rock, Ark., field director of the A. M. A. Council on Rural Health, will be guest speakers at the ninth Annual Rural Health Conference at Jackson's Mill, Oct. 4. Dr. Jerome C. Arnett, Rowlesburg, chairman, West Virginia State Medical Association's committee on rural health, will be in charge of the meeting, which is being sponsored by the association in cooperation with the West Virginia Farm Bureau, the agricultural extension division of West Virginia University, the West Virginia Congress of Agriculture, the West Virginia Home Demonstration Council, and the state department of health. During the morning session, workshops will be conducted on the possible contributions of youth to rural health, the role of the family physician in rural health, the role of public health in rural health services, and hospital and nursing care facilities. All those attending the conference will be guests of the West Virginia State Medical Association at a luncheon, 12:30 p. m. The afternoon session will be opened at 1:30 p. m. with an address of welcome by Dr. Athey R. Lutz of Parkersburg, president of the state medical association, followed by the addresses of Dr. Crockett and Mr. Gates. A panel discussion, with Mr. Gates as moderator, will follow his address. The conference is open to members of all interested groups.

GENERAL

Conference on Recreation.—The International Recreation Congress will convene at the Bellevue-Stratford Hotel in Philadelphia, Sept. 30—Oct. 5 coincidentally with the National Recreation Congress, which will hold its 38th annual meeting and observe the 50th anniversary year of the National Recreation Association, a citizens' organization supported by voluntary contributions.

SMA Golden Anniversary.—The Southern Medical Association, which will hold its regular annual scientific session, Nov. 12-15 in Washington, D. C., will celebrate its golden anniversary with a special program at the Read House, Chattanooga, Tenn., Oct. 2-3. Dr. Dwight H. Murray, Napa, Calif., President of the American Medical Association, will represent the A. M. A. at the celebration. After a dinner meeting Tuesday evening, Dr. Robert L. Sanders, Memphis, immediate past-president of the Southern Medical Association, will have as his subject "Fifty Years of Medicine in the South." A feature of the Wednesday morning session will be the unveiling of a plaque to be placed on the Read House.

Outbreak of Typhoid.—According to the U. S. Public Health Service, a number of cases of typhoid have occurred among persons who attended a church convention in Monarch Springs, Mo., July 20-29. A total of 170 families, comprising about 400 persons from 14 states, are reported to have attended the convention of the Church of God. By Aug. 25 two confirmed and three suspect cases with one death had been discovered in Louisiana among persons who had returned. There was a fatal suspect case and a reported case in Oklahoma, two reported cases in California, and one in Missouri. A subsequent report (Aug. 30) from the Missouri Division of Public Health noted that seven suspect cases had been found in Newton County among 25 of the camp meeting attendants. Preliminary investigation revealed that a well used by those at the convention was contaminated. A phage type C_2 organism has been isolated in one case.

Philippine Hospital Director on Tour.—Dr. Jose R. Reyes, past-president of the Manila Medical Society and the Philippine Obstetrical and Gynecological Society, is on a three to six months' travel grant in the United States to study the operation of selected teaching hospitals connected with university medical schools. Dr. Reyes is the director of the North General Hospital in Manila, a newly constructed 350-bed hospital of the department of health, the first official training hospital of the department wherein both pre-service and in-service training will be offered to many categories of health personnel and where refresher courses for doctors, nurses, dietitians, and others are being made available. Dr. Reyes, a graduate of the University of the Philippines College of Medicine, Manila, is a professor of gynecology at the Far Eastern University Institute of Medicine and an associate clinical professor of the University of Santo Tomas Faculty of Medicine and Surgery, both in Manila. Information may be obtained from Dr. John J. Hanlon, Chief, Public Health Branch, International Cooperation Administration, Washington 25, D. C.

Clinical Congress of Surgeons in San Francisco.—The 42nd annual Clinical Congress of the American College of Surgeons will convene in San Francisco, Oct. 8-12, under the presidency of Dr. Warren H. Cole, Chicago. Headquarters will be at the Civic Auditorium; some of the scientific sessions are scheduled for the Fairmont and Mark Hopkins hotels. For the first time, student representatives from 16 medical schools will attend the clinical congress, at college expense. The program will include eight postgraduate courses, 27 panel discussions, color television from the Herbert C. Moffitt Hospital, 17 cine clinics, motion pictures, surgical forum sessions, scientific and technical exhibits, and symposiums on trauma, cancer, graduate training in surgery and the surgical specialties, and mobilization of the stapes in otosclerosis, as well as a motion picture symposium on new or unusual problems in surgery. Major addresses will be presented by Dr. Daniel C. Elkin, Lancaster, Ky., incoming president of the college, and by Vannevar Bush, Sc.D., Washington, D. C., who will deliver the Martin Memorial Lecture. Dr. Michael L. Mason, Chicago, secretary of the college, will give the annual oration on trauma, speaking on "The Treatment of Open Wounds." The annual business meeting of the American branch of the International Society of Surgery will be held on Oct. 9 at 4 p.m. in the Nob Hill Room at the Fairmont Hotel.

Anesthesiologists Meet in Kansas City.—The annual meeting of the American Society of Anesthesiologists will convene in Kansas City, Mo., Oct. 8-12, under the presidency of Dr. Scott M. Smith, Salt Lake City. The general scientific sessions will be held in the Municipal Auditorium and, concurrently, another educational program, "Work in Progress," in the Little Theater of that building. The general sessions will include a panel discussion, "Anesthesia for Cardiac Catheterization," Wednesday, 2-3:30 p. m., moderated by Dr. Howard A. Bennett, Tulsa, Okla., and a panel discussion, "Pain Control in Terminal or Inoperable Carcinoma," at the same time on Thursday afternoon, with Dr. Richard H. Barrett, Hanover, N. H., as moderator. The general sessions will open Wednesday, 9 a. m., with "Chemical Rhizotomy in Management of Intractable Pain" by Dr. Louis W. Lewis, Ann Arbor, Mich., and will close with a debate, "Resolved That, Purism is Preferable to Poly-Pharmacy in the Practice of Anesthesia." The affirmative will be presented by Drs. O. Sidney Orth, Madison, Wis., and Perry P. Volpitto, Augusta, Ga., and the negative by Drs. M. Jack Frumin, New York, and Heber H. Ryan, Glendale, Calif. "Work in Progress" will begin with a panel discussion Wednesday, "The Performance of Equipment in Inhalation Anesthesia," moderated by Dr. Emanuel M. Papper, New York. The Tuesday morning session will open with panel discussion on pulmonary edema, for which Dr. Charles R. Stephen, Durham, N. C., will serve as moderator, and the Friday morning session with a panel discussion, "Anesthesia for Intracardiac Surgery," with Dr. Frederick H. Van Bergen, Minneapolis, as moderator. Monday and Tuesday will be devoted to the seventh annual refresher course, sponsored by the committee on medical schools and postgraduate education.

Tennessee Valley Medical Assembly.—The fourth annual Tennessee Valley Medical Assembly will be held at the Read House, Chattanooga, Tenn., Oct. 1-2. The registration fee ($15) includes the banquet Monday evening, at which Dr. Frederick C. Schwarz, Sydney, Australia, will present "Diagnosis, Prognosis and Treatment of Communism." At the scientific session Dr. Dwight H. Murray, Napa, Calif., President of the American Medical Association, will consider "The Role of the A. M. A. in Improving and Increasing Scientific Programs Throughout the Country." Other guest speakers and their subjects include:

alter C. Alvarez, Chicago, New Observations on Little Strokes.
hilip S. Hench, Rochester, Minn., Treatment of Rheumatoid Arthritis.
J. P. Greenhill, Chicago, What's New in Obstetrics.
Guy W. Horsley, Richmond, Va., Carcinoma of the Colon and Rectum.
Eugene P. Pendergrass, Philadelphia, Responsibility of the General Practitioner and the Radiologist in Diagnosis of Curable Cancer of the Lung.
Tom D. Spies, Birmingham, Ala., Recent Advances in Treatment of Nutritional Disorders.
Francis E. Senear, Chicago, Diagnosis and Treatment of the Bullous Dermatoses.
James L. Poppen, Boston, Indications for Sympathectomy.
Henry W. Cave, New York, Ulcerative Colitis
Russell J. Blattner, Houston, Texas, Encephalitis.
J. Hartwell Harrison, Boston, Clinical States Due to Abnormal Adrenocortical Function.
Henry L. Bockus, *Philadelphia*, Chronic Regional Enteritis The Acute Abdomen.
Robert E. Gross, Boston, Surgical Treatment for Interauricular Septal Defects.
John S. Lundy, Rochester, Minn., Pain Relief
T. Campbell Thompson, New York, Orthopedic Conditions of Special Interest to the Pediatrician and General Practitioner.
Michael E. DeBakey, Houston, Texas, Surgical Treatment of Diseases of the Aorta.

Congress on Medical Records.—The second International Congress on Medical Records will convene at the Shoreham Hotel, Washington, D. C., Oct. 1-5, under the joint sponsorship of the American Association of Medical Record Librarians, the Association of Medical Record Officers of the United Kingdom, the Canadian Association of Medical Record Librarians, and the Australian Federation of Medical Record Librarians. The opening address, "Establishing Standards and Evaluating Patient Care," will be delivered Monday morning by Dr. Mindel C. Sheps, department of preventive medicine, Harvard Medical School, Boston. The Monday sessions will close with "World Health Problems and Programs" by Howard M. Kline, Ph.D., chief, education and training branch, division of international health, Public Health Service, Department of Health, Education, and Welfare, Washington, D. C. Tuesday afternoon Dr. Gordon A. Winfield, director, medical research statistics, development and planning, Department of Veterans Affairs, Ottawa, Canada, will moderate a panel in which principles of selection and use of morbidity and mortality classifications will be presented (1) in vital and health statistics by Dr. Halbert L. Dunn, chief, National Office of Vital Statistics, Public Health Service, Department of Health, Education, and Welfare, Washington, D. C.; (2) in clinical medicine by Dr. George Baehr, New York City, chairman, Editorial Advisory Board, A. M. A. Standard Nomenclature of Diseases and Operations; and (3) in industrial medicine by Dr. Jean S. Felton, associate professor of medicine and of preventive medicine and public health, University of Oklahoma School of Medicine, Oklahoma City. Wednesday afternoon will be devoted to tours of these local hospitals: National Naval Medical Center and Clinical Center, National Institutes of Health, Public Health Service, Department of Health, Education, and Welfare in Bethesda, Md., and Johns Hopkins Hospital and U. S. Public Health Service Hospital in Baltimore. (Only one tour may be taken by any individual). The Thursday morning program will conclude with "The Need for Research in Mental Health Problems" by Dr. Richard L. Jenkins, director, Psychiatric Evaluation Project, Veterans Administration Hospital, Washington, D. C. The Sister Patricia Memorial Lecture, "Changing Concepts of Treatment," will be delivered Friday morning by Dr. William S. Middleton, chief medical director, Veterans Administration, Washington, D. C.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

	Aug. 25, 1956

Fellowship in Hematology.—A fellowship in hematology, with emphasis on the study of leukemia, has been created in the University of Cincinnati College of Medicine by friends of the late Mrs. A. Burton Closson. The Lucinda Closson Memorial Fellowship in the Laboratory of Hematology and Cellular Metabolism at the Cincinnati General Hospital will be under the direction of Dr. Richard W. Vilter. A stipend of $3,500 will be paid to first-year appointees and $4,500 to second-year appointees. An internship and one or more years of residency training in internal medicine are required. Openings are available beginning July, 1957. Applications should be directed to Dr. Richard W. Vilter, Director, Laboratory of Hematology, Cincinnati General Hospital, Cincinnati 29.

FOREIGN

Geriatric Symposium.—A symposium on the biology of aging will be held in the Anatomy Theatre, University College, Gower Street, London, W. C. 1, Sept. 27-28. Subjects for discussion will include Aging and Metabolism, The Aging of Mammalian Cells, Endocrinology and Aging, Functional Changes with Age in Relation to the Employment of the Elderly, Psychological Changes with Age, Nutrition and Aging, and Genetic Variations in Aging.

Congress on History of Pharmacy.—The International Society for the History of Pharmacy will hold its annual congress Oct. 4-8 at Lucerne, Switzerland. On Saturday an excursion to the Lake Valley has been arranged, with reception at Heidegg Castle. Sunday there will be a session on Buergenstock, commemorating 30 years of the International Society for the History of Pharmacy, the centenary of Prof. Alexander Tschirch, and the memory of Prof. Josef A. Haefliger, president of the society till 1954. A visit to the Swiss Museum for the History of Pharmacy has been planned for Monday. Registration forms can be obtained from Dr. Albert Schubiger, Kapellplatz 5, Lucerne, Switzerland.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers. September 4-5 (Part I). Candidates may file applications at any time but they must be received at least six weeks before the date of the examination for which application is made. New candidates should apply by formal registration; registered candidates may notify the board, indicating desired location, date and candidate number. Ex. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 18-20. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Arizona:* *Examination and Reciprocity.* Phoenix, Oct. 17-19. Ex. Sec., Mr. Robert Carpenter, 411 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, Nov. 8-9. Sec., Dr. Joe Verser, Harrisburg.

Colorado:* *Reciprocity.* Denver, Oct. 9. Final date for filing application was Sept. 10. *Examination.* Denver, Dec. 4-5. Final date for filing application is Nov. 2. Sec., Dr. Samuel H. Brown, 831 Republic Bldg., Denver 2.

Connecticut:* *Examination.* Hartford, Nov. 13-15. Sec., Dr. Creighton Barker, 160 St. Roman St., New Haven.

Delaware: *Examination.* Dover, Jan. 8-10. *Reciprocity.* Dover, Jan. 17. Sec., Dr. Joseph S. McDaniel, 225 So. *State St., Dover.*

District of Columbia:* *Examination.* Washington, Nov. 13-14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington 6.

Florida:* *Examination.* Miami Beach, Nov. 25-27. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, Oct. 9-11. Sec., Mr. Cecil L. Clifton, 111 State Capitol, Atlanta 3.

Idaho: *Examination and Reciprocity.* Boise, Jan. 7-9. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination.* Chicago Sept. 24-27. Supt. of Regis., Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Kansas: *Examination and Endorsement.* Topeka, Dec. 12-13. Sec., Dr. Lyle F. Schmaus, 872 New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 10-12. Sec., Dr. Russell Teague, 620 South Third St., Louisville 2.

Louisiana: *Homeopathic.* Subject to call. Sec., Dr. F. H. Hardenstein, 903 Pere Marquette Bldg., New Orleans 12.

Maine: *Examination and Reciprocity.* Portland, Nov. 13-14. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Examination.* Baltimore, Dec. 11-14. Sec., Dr. Lewis P. Gundry, 1211 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Lansing, Oct. 10-12. Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., West Michigan Ave., Lansing 8.

Minnesota:* *Examination and Reciprocity.* Minneapolis, Oct. 16-18. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 12.

Mississippi: *Reciprocity.* Jackson, December. *Examination.* Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Old Capitol, Jackson.

Missouri: *Examination and Reciprocity.* Kansas City, Oct. 25-27. Ex. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Montana: *Examination and Reciprocity.* Helena, Oct. 2-3. Sec., Dr. S. A. Cooney, 7 West 6th Ave., Helena.

Nebraska:* *Examination.* Omaha, June 17-19. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada:* *Examination and Reciprocity.* Reno, Oct. 2. Sec., Dr. G. H. Ross, 112 No. Curry St., Carson City.

New Jersey: *Endorsement.* Trenton, Sept. 12. *Examination.* Trenton, Oct. 16-19. Sec., Dr. Patrick H. Corrigan, 28 West State St., Trenton.

New Mexico:* *Examination and Reciprocity.* Santa Fe, Nov. 19-20. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York City and Syracuse, Oct. 16-19. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Examination and Reciprocity.* Raleigh, Sept. 24. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: Examination and Reciprocity. Grand Forks, Jan. 2-5. Sec., Dr. C. J. Glaspel, Grafton.

Oregon:* *Reciprocity.* Portland, Oct. 19-20. *Examination.* Portland, January. Ex. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Rhode Island:* *Examination.* Providence, Oct. 4-5. Admin. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota:* *Examination.* Sioux Falls, Jan. 21-22. Ex. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* Examination. Memphis, Sept. 26-27. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:* *Examination and Reciprocity.* Fort Worth, Dec. 6-8. Applications for reciprocity must be complete and on file at least thirty days prior to the December meeting, and applications for examination must be complete and on file at least ten days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah. *Reciprocity.* Salt Lake City, Nov. 20. *Examination.* Salt Lake City, July 11-13. Director, Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: *Examination and Reciprocity.* Richmond, Dec. 5-7. Address: Secretary to the Board, 631 First St., S.W., Roanoke.

Washington:* *Examination and Reciprocity.* Seattle, Jan. 14-16 and Jan. 12. Sec., Mr. Edward C. Dohm, Olympia.

West Virginia: *Reciprocity.* Charleston, Oct. 8. *Examination.* Charleston, January. Sec., Dr. Newman H. Dyer, State Office Building No. 3, Charleston 5.

Wisconsin:* *Reciprocity.* Madison, Oct. 19 and Jan. 9. *Examination.* Madison, Jan. 8-10. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., 1 West Wilson St., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, Oct. 1. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

Alaska:* On application in Anchorage, Fairbanks, Juneau and *other towns. Sec., Dr. W. M. Whitehead.* 172 South Franklin St., Juneau.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arkansas: *Examination and Reciprocity.* Little Rock, Oct. 1-2. Sec., Mr. S. C. Dellinger, Zoology Department, University of Arkansas, Little Rock.

Colorado: *Examination and Reciprocity.* Dec. 5-6, Lincoln and Denver. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination.* New Haven, Oct. 13. Exec. Asst., Miss Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 22-23. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington.

Michigan: *Examination and Reciprocity.* Ann Arbor and Detroit, Oct. 12-13. Sec., Mrs. Anne Baker, 116 Stevens T. Mason Bldg., Lansing.

Minnesota: *Examination and Reciprocity.* Minneapolis, Oct. 2-3. *Sec.,* Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

New Mexico: *Reciprocity.* Santa Fe, Oct. 2. Examination. Santa Fe, Oct. 21. Sec., Mrs. Marguerite Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination and Reciprocity.* Oklahoma City, Sept. 28-29. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Dec. 1. Dr. Earl M. Palett, Sec., State Board of Higher Education, Eugene.

South Dakota. *Examination.* Vermillion, Dec. 7-8. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Texas: Reciprocity. Dallas, Sept. 29. *Examination.* Dallas, Oct. 19-20. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Washington: *Examination.* Seattle, Jan. 9-10. Sec., Mr. Edward C. Dohm, Olympia.

Wisconsin: *Examination.* Milwaukee, Dec. 1. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

Alaska: *Examination and Reciprocity.* Anchorage and Juneau, first week of February, April, June, August and November. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

GOVERNMENT SERVICES

ARMY

First-Aid Training.—Today's soldier for the first time is getting extensive indoctrination in the basic medical essentials for saving his own life and that of his fellow soldier in mass destruction warfare. More than a year ago the Army Medical Service began establishing standards of proficiency to be reached by nonmedical soldiers that would enable them to assist the injured and save their own lives when faced with overwhelming casualties. Recognizing that recent changes in weapons and the advent of nuclear arms had made necessary an increase in the amount of self-aid and first aid being taught the average soldier, the surgeon general suggested such indoctrination be given by Army Medical Service personnel stationed at each training center. A class of 10 officers and 30 enlisted men, selected to carry out the objective of the new program, took five days of intensive training at the Army Medical Service School, Fort Sam Houston, Texas, in April. When graduated, they were organized into six groups of officers and enlisted men and sent to Fort Dix, N. J.; Fort Jackson, S. C.; Camp Chaffee, Ark.; Fort Leonard Wood, Mo.; Fort Knox, Ky.; and Fort Bliss, Texas.

The amount of instruction in the principles of self-aid and first aid needed by the combat soldier for future wars is just about twice the training he has needed for the conventional warfare of the past. The medical training now being inaugurated at the training centers is based on the assumption that in the future nonmedical military personnel will have to bear far greater responsibility for first-aid treatment for themselves and their colleagues than previously. These persons will be equipped by the new program of instruction to assist the supporting medical units and will significantly bring about conservation of manpower. The broadened concept of soldier first aid and self-aid includes the control of hemorrhage; the prevention and treatment of shock; patient positioning and care in the treatment of fractures; the care of open wounds and burns; artificial respiration; treatment of casualties with wounds in chest, head, neck, extremities; and a working knowledge of the screening and sporting of the wounded.

Medical Aspects of World War II.—The growth of the Army Medical Service during World War II to an organization that was able to treat almost 9 million patients in the United States is described in a new volume of the Army *Historical Series* entitled "The Medical Department: Hospitalization and Evacuation, Zone of Interior," which was published in July. The book was written by Clarence McK. Smith, formerly a member of the historical division, Office of the Army Surgeon General. This new volume may be purchased for $4 from the Superintendent of Documents, Government Printing Office, Washington 25, D. C.

Personal.—Brig. Gen. Sam F. Seeley, M. C., U. S. Army, for nearly three years chief consultant in surgery to the U. S. Army in Europe, has assumed command of the 1,000-bed Valley Forge Army Hospital, succeeding Brig. Gen. Mack M. Green, M. C., who retired on June 30.

NAVY

Medical Student Ensigns.—One hundred fifty-five selected senior students enrolled in 57 medical schools throughout the United States and Puerto Rico will enter on active duty as medical ensigns, U. S. Naval Reserve, and participants in the Navy's senior medical student program when school opens in the fall. These students will receive the full pay and allowance of their rank while enrolled on active duty, and on completion of medical school and internship they will be commissioned in the medical corps of the regular Navy. This program is open to qualified students enrolled at medical schools accredited by the Council on Medical Education and Hospitals of the American Medical Association. Students who have completed their second year of medical school may make application for this training at any office of naval officer procurement. Active duty commences and continues while the students are in attendance during their senior academic year. To be eligible for participation, the student must be a medical ensign, U. S. Naval Reserve, or agree to accept such an appointment if selected. A board convened in the bureau of medicine and surgery selects the candidates for participation in this program. Because an average of four months is required to process each application completely, those desiring to participate in this training during fiscal year 1958 must forward completed applications by Feb. 1, 1957, to the Bureau of Personnel, Department of the Navy, Washington, D. C.

VETERANS ADMINISTRATION

Personal.—Dr. Ivan F. Bennett has been appointed chief of psychiatric research in the psychiatry and neurology service of the Veterans Administration Central Office, Washington, D. C. He succeeds Dr. Richard L. Jenkins, who has been reassigned as director of the VA's psychiatric evaluation project, with headquarters in Mount Alto Hospital in Washington.—Dr. Marjorie P. Wilson has been appointed chief of the Veterans Administration residency and internship division in the education service of the *Department of Medicine and Surgery* at Washington, D. C. She succeeds Dr. J. H. Friedlander, who has been reassigned as manager of the VA hospital in Big Springs, Texas.—The highest honor in the physical medicine and rehabilitation medical service, the John E. Davis plaque, has been awarded to Dr. Louis B. Newman, chief of physical medicine and rehabilitation at the Chicago north side VA Research Hospital.

PUBLIC HEALTH SERVICE

Research Fellowships.—A Senior Research Fellowship program, administered by the *National Institutes of Health*, Public Health Service, is now in operation. During the first year, this program will provide for a total of 40 to 50 awards to the nation's medical schools, dental schools, and schools of public health. These awards will be increased by a like number each year for five years until a total of 200 to 250 fellowships is awarded annually. The awards will be for a maximum of $10,000 a year and may be retained as long as five years. Only three applications may be made per year by each school. The program is designed to attract and hold able investigators in the preclinical sciences. Requests for information concerning this program should be addressed to the Chief, Research Fellowship Program, Division of Research Grants, *National Institutes* of Health, Bethesda 14, Md.

Postgraduate Courses.—The Graduate School of the U. S. Department of Agriculture, in cooperation with the National Institutes of Health in Bethesda, Md., has been offering a series of postgraduate courses for physicians. Some of these courses are unusual, for example, there is a series of courses entitled "Improving Professional Speaking" that has been constructed and oriented specifically for physicians. An article entitled "Speech Education for Physicians and Dentists" is scheduled for publication in the January, 1957, issue of *Today's Speech.*

FOOD AND DRUG ADMINISTRATION

Personal.—Dr. Peter J. Farago has been appointed deputy medical director of the Food and Drug Administration, Department of Health, Education, and Welfare. The administration's Bureau of Medicine is responsible for advising the administration on all medical questions involved in enforcement of the Federal Food, Drug, and Cosmetic Act. The bureau also assists in the development of medical evidence in court cases involving adulterated and misbranded products and administers the new-drug provisions of the act that require review of safety data on all new drugs prior to marketing. Dr. Farago comes to the Food and Drug Administration from the Abbott Laboratories, North Chicago, where he has been a member of the medical department doing clinical investigative work on new drugs for the past three years.

DEATHS

Carlson, Anton Julius, formerly professor and chairman of the department of physiology at the University of Chicago, and in 1946 recipient of the Distinguished Service medal of the American Medical Association, died Sept. 2 in Albert Merritt Billings Hospital, of cancer. Dr. Carlson was born in Sweden Jan. 29, 1875, and came to America in 1891. He received the bachelor of science degree from Augustana College in 1898 and the Ph.D. from Stanford University in 1903. He served as research assistant in physiology at Stanford and then became associated with the Carnegie Institution. In 1904 he joined the faculty of the University of Chicago, where in 1929 he became Frank P. Hixon Distinguished Service Professor. He was Secretary of the Section on Pathology and Physiology of the American Medical Association from 1912 to 1914, when he became Chairman, serving until 1915. He received the Distinguished Service Citation of the Minnesota State Medical Association and in 1953 was voted humanist of the year. He was president of the American Physiological Society, the Institute of Medicine of Chicago, American Association of University Professors, Federation of American Societies for Experimental Biology, the Gerontological Society, American Biological Society, American Association for the Advancement of Science, National Society for Medical Research, Research Council on Problems of Alcohol, and the Chicago Committee on Alcoholism. During World War I he was assigned to the Sanitary Corps as a lieutenant colonel in the U. S. Army and worked with the American Relief Expedition in Europe. He was awarded honorary degrees (M.D., LL.D., and Sc.D.) by eight universities and colleges.

Fulton, Clifford Cannon ⊕ Oklahoma City; Rush Medical College, Chicago, 1929; professor of surgery at the University of Oklahoma School of Medicine; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; veteran of World War II; on the staffs of St. Anthony and Wesley hospitals; died June 22, aged 53, of cancer of the liver.

Grimm, Benjamin Hayes ⊕ Sidney, Neb.; University of Nebraska College of Medicine, Omaha, 1936; interned at the Presbyterian Hospital in Denver; on the faculty of his alma mater; member of the American Academy of General Practice; on the staff of the Cheyenne County Memorial Hospital, where he died May 31, aged 46, of coronary occlusion.

Horvath, Louis Oliver ⊕ Detroit; Wayne University College of Medicine, Detroit, 1938; interned at the Grace Hospital; on the staffs of the Delray and William Booth Memorial hospitals; died June 13, aged 51, of coronary thrombosis.

Hurley, Douglas Chester ⊕ Elgin, Ill.; Northwestern University Medical School, Chicago, 1925; veteran of World Wars I and II, died July 15, aged 57.

Jacobsen, Frederick Charles, Palos Heights, Ill.; Jenner Medical College, Chicago, 1907; veteran of the Spanish-American War, retired chief surgeon for Armour and Company in Chicago, served on the staff of the Mercy Hospital in Chicago, where he died March 5, aged 80, of uremia due to carcinoma.

Johnson, Frederick A., New York City; Columbia University College of Physicians and Surgeons, New York City, 1906; died May 28, aged 82, of arteriosclerotic heart disease.

Kimmel, Richard Klais, St. Louis; Washington University School of Medicine, St. Louis, 1925; died in De Paul Hospital June 3, aged 55, of hypertensive arteriosclerotic cardiovascular disease.

Krieger, Jacob, Brooklyn, N. Y.; Long Island College Hospital, Brooklyn, 1913; member of the Medical Society of the State of New York; member of the staff of the Beth-El Hospital, where he died June 26, aged 65, of acute myocardial infarction and arteriosclerotic heart disease.

Lanza, Nicola, New York City; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1898; died in the Flower and Fifth Avenue Hospitals June 9, aged 83, of bronchogenic carcinoma.

Lloyd, John Robert ⊕ Washington, D. C.; Indiana University School of Medicine, Indianapolis, 1925; veteran of World War I; on the staff of the Episcopal Eye, Ear and Throat Hospital; died in Chevy Chase, Md., July 3, aged 57, of coronary occlusion.

Love, Andrew Alexander ⊕ North Hollywood, Calif.; University of Minnesota Medical School, Minneapolis, 1930; also a graduate of a dental school; certified by the National Board of Medical Examiners; fellow of the American College of Surgeons; veteran of World War I; industrial surgeon at Lockheed Aircraft Corporation at Burbank; on the courtesy staff of St. Joseph Hospital in Burbank, where he died June 12, aged 57, of generalized peritonitis and pneumonia.

Lucas, Charles, Los Angeles; Georgetown University School of Medicine, Washington, D. C., 1893; died April 11, aged 89, of cancer of the lung.

McCall, Cummings Herrington ⊕ Gulfport, Miss.; Rush Medical College, Chicago, 1928; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; past-president of the Mississippi State Medical Association and the Coast Counties Medical Society; on the staff of the Memorial Hospital; died July 2, aged 59.

McKinley, Walter Etna ⊕ Gardner, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1887; member of the American Psychiatric Association; served on the staff of the Osawatomie (Kan.) State Hospital; died July 12, aged 88, of left ventricular failure, arteriosclerosis, and hypertension.

McLaughlin, Bernard Gill, Manchester, N. H.; Georgetown University School of Medicine, Washington, D. C., 1951; interned at the Georgetown University Hospital in Washington, D. C., where he served a residency; served a residency at the New England Deaconess Hospital in Boston and the Veterans Administration Hospital in Washington, D. C.; certified by the National Board of Medical Examiners; died in the Sacred Heart Hospital March 18, aged 29, of chronic glomerulonephritis, hypertensive cardiovascular disease, and diabetes mellitus.

Maloney, Robert Lee ⊕ McMinnville, Tenn.; Atlanta (Ga.) College of Physicians and Surgeons, 1903; chairman of the Magness Memorial Library Board; a director of the First National Bank of McMinnville and the First Federal Bank of Nashville; died July 8, aged 81, of heart disease.

Martinolich, Betty Joyce Drury, Byhalia, Miss.; University of Tennessee College of Medicine, Memphis, 1953; served on the staff of North Mississippi Hospital in Holly Springs; interned at St. Joseph's Hospital in Memphis, Tenn.; died July 7, aged 29, of cerebrovascular accident.

Mount, Garry, Rochester, N. Y.; Cleveland Homeopathic Medical College, 1899; an associate member of the American Medical Association; served on the staff of the Genesee Hospital; died July 8, aged 79, of coronary disease.

Paster, Alexander Zus ⊕ New York City; Universita Karlova Fakulta Lékařská, Praha, Czechoslovakia, 1929; died in the Flower and Fifth Avenue Hospitals June 17, aged 55, of cirrhosis of the liver.

Plummer, Grover Cleveland ⊕ Buffalo, Mo.; University College of Medicine, Richmond, Va., 1909; member of the American Academy of General Practice; died in the Springfield (Mo.) Baptist Hospital, May 17, aged 70, of coronary thrombosis and arteriosclerosis.

Reynolds, Ralph Arthur ⊕ San Francisco; University of California Medical School, San Francisco, 1925; member of the Endocrine Society; died June 25, aged 63, of coronary thrombosis.

Rodman, George Teeter, Hawley, Pa.; University of the City of New York Medical Department, 1886; past-president of the Wayne County Medical Society; secretary of the first local board of health, which he helped to organize; died June 13, aged 91, of arteriosclerosis.

⊕ Indicates Member of the American Medical Association.

Rupp, John Jacob ⊕ Marlboro, Mass.; Washington University School of Medicine, St. Louis, 1944; interned at the University Hospitals in Cleveland; formerly a resident at the Albany (N. Y.) Hospital and the Massachusetts General Hospital in Boston; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthesiologists; and the Arizona State Medical Association; died June 15, aged 37.

St. George, Archibald, South Swansea, Mass.; College of Physicians and Surgeons, Baltimore, 1895; served as a member of the board of health; died June 16, aged 88.

Saidman, Maurycy ⊕ New York City; Universität Basel Medizinische Fakultät, Switzerland, 1907; fellow of the International College of Surgeons; died in the Maimonides Hospital in Brooklyn June 27, aged 71, of arteriosclerotic heart disease.

Salvati, Carlo, New York City; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1893; died May 31, aged 90, of arteriosclerotic heart disease.

Shelley, Robert Alexander J. ⊕ Coldwater, Kan.; University of Tennessee Medical Department, Nashville, 1903; died in the Comanche County Hospital July 3, aged 81, of cancer.

Simmons, James I., Dallas, Ga.; Atlanta (Ga.) College of Physicians and Surgeons, 1909; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1910; died June 15, aged 75.

Skern, Abraham Marcus, Yonkers, N. Y.; Cornell University Medical College, New York City, 1902; an associate member of the American Medical Association; died in New York City July 8, aged 75, of coronary arteriosclerosis.

Skiff, Stuart Ernest ⊕ New Haven, Conn.; Hahnemann Medical College and Hospital of Philadelphia, 1903; one of the founders of the Grace-New Haven Community Hospital, where he was on the staff for many years; died June 3, aged 77, of cerebral hemorrhage.

Smith, Frederick Cleveland ⊕ Marion, Ohio (licensed in Ohio in 1917); served as Republican congressman from the Eighth Ohio Congressional District; formerly mayor of Marion; died in the Marion General Hospital July 16, aged 72.

Solomonica, Julius, New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1901; died in the Mount Sinai Hospital June 11, aged 82, of congestive heart disease and myocardial infarct.

Stack, Leonard Anthony ⊕ Lorain, Ohio; University of Cincinnati College of Medicine, 1923; fellow of the American College of Surgeons; past-president of the Lorain County Medical Society; veteran of World Wars I and II; past-president of the staff and member of the board of directors of St. Joseph's Hospital, where he died June 19, aged 57, of brain tumor.

Stafford, Samuel Patterson, St. Louis; University of Pennsylvania Department of Medicine, Philadelphia, 1897; died in the Homer G. Phillips Hospital July 1, aged 84, of heart disease.

Stephens, John Arch ⊕ Paris, Texas; Baylor University College of Medicine, Dallas, 1929; member of the American Academy of General Practice; died June 29, aged 51, of coronary thrombosis.

Stevens, Franklin Augustus, Jr., New York City; State University of Iowa College of Medicine, Iowa City, 1915; served as an associate in medicine at Columbia University College of Physicians and Surgeons; later assistant attending physician at the Vanderbilt Clinic and Presbyterian Hospital, where he died June 20, aged 64, of carcinoma of the lung.

Stevens, George Alfred ⊕ Sioux Falls, S. D.; Creighton University School of Medicine, Omaha, 1909; on the staff of the Sioux Valley Hospital; died June 20, aged 71, of a heart attack.

Sudler, Mervin Tubman ⊕ Lawrence, Kan.; College of Physicians and Surgeons, Baltimore, 1901; instructor in surgery at the Cornell University Medical College in New York City, 1902-1903; professor of anatomy at the University of Kansas School of Medicine, Kansas City, from 1906 to 1912 when he became dean and professor of surgery, serving until 1924; fellow of the American College of Surgeons; on the staff of the Lawrence Memorial Hospital; consultant, Watkins Memorial Hospital; died June 22, aged 80, of coronary occlusion.

Tappan, Russell G. ⊕ Knoxville, Tenn.; St. Louis College of Physicians and Surgeons, 1922; died in Fort Sanders Presbyterian Hospital June 15, aged 59.

Teifer, Charles Aloyscious ⊕ Muskegon, Mich.; Detroit College of Medicine and Surgery, 1916; past-president of the Muskegon County Medical Society; member of the Industrial Medical Association; at one time a member of the Michigan State Board of Registration in Medicine; for many years physician for Muskegon High School football teams and other high school athletes; died in the Mercy Hospital June 6, aged 64, of acute posterior myocardial infarction.

Thomas, John Willard, New Orleans; Harvard Medical School, Boston, 1900; served on the faculty of Flint Medical College of New Orleans University; on the staff of the Flint-Goodridge Hospital of Dillard University; died June 21, aged 96.

Thornton, Robert Amos ⊕ Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1912; veteran of World War I; on the staffs of St. Anthony and White Cross hospitals; died May 20, aged 67, of coronary thrombosis.

Thorpe, Eugene Davis, Madison, Fla.; Tulane University School of Medicine, New Orleans, 1920; veteran of World War I; died May 16, aged 61, of a heart attack.

Trudeau, Francis Berger ⊕ Saranac Lake, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1913; member of the American Trudeau Society and the American Clinical and Climatological Association; consultant, member and past-president of the board of the Trudeau Sanatorium in Trudeau; honorary staff member of General Hospital; died July 19, aged 69, of arteriosclerotic heart disease.

Van Haltern, Harold Leslie ⊕ Pontiac, Mich.; University of Texas School of Medicine, Galveston, 1933; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; radiologist at the Pontiac General Hospital, where he died June 23, aged 48, of coronary thrombosis.

Welch, Francis William, Buffalo; University of Buffalo School of Medicine, 1914; served on the staff of the Lafayette General Hospital; died in the Edward J. Meyer Memorial Hospital July 2, aged 64.

Welch, John Gober ⊕ Port Neches, Texas; Southern Methodist University Medical Department, Dallas, 1914; died in St. Mary's Hospital, Port Arthur, June 3, aged 63.

Weldon, Thomas Franklin, Major, U. S. Army, retired, Hicksville, N. Y.; Long Island College Hospital, Brooklyn, 1914; entered the Medical Corps of the U. S. Army on July 1, 1920; retired Dec. 31, 1939; died in the Veterans Administration Hospital in Brooklyn, June 28, aged 64, of bronchopneumonia and glioblastoma multiforme.

Wertheim, Leopold Leo, Philadelphia; Columbia University College of Physicians and Surgeons, New York City, 1905; member of the Medical Society of the State of New York; died in the Hospital of the University of Pennsylvania, April 6, aged 70, of myocardial infarction.

White, Charles Peyton, Birmingham, Ala.; Memphis (Tenn.) Hospital Medical College, 1910; died in the Carraway Methodist Hospital June 17, aged 78, of cerebral thrombosis and cerebral arteriosclerosis.

White, Edwin Clay ⊕ Kansas City, Mo.; Rush Medical College, Chicago, 1913; veteran of World War I; member of the state board of medical examiners; twice served terms as president of the medical staff at St. Joseph Hospital and was on the staff of St. Luke's Hospital when it opened; served as a staff member of the Kansas City General Hospital; associate editor of the *Weekly Bulletin of the Jackson County Medical Society;* died June 20, aged 68, of acute inflammation of the pancreas.

Wood, Maurice Tilghman ⊕ Eugene, Ore.; University of Oregon Medical School, Portland, 1940; died in San Francisco May 24, aged 46.

Yocum, Lincoln Abraham, Wooster, Ohio; Marion-Sims College of Medicine, St. Louis, 1895; for 21 years a member of the board of health; on the staff of the Wooster Community Hospital; died May 21, aged 89, of infirmities of age.

ISRAEL

Blood Lipid Levels.—Daniel Brunner reported at a meeting of the Jewish Medical Association in Tel Aviv in July that a fine opportunity exists in Israel for research on blood lipid levels among various communities, because, as a sequel to the enormous immigration, Jews from the western world mix with those who have immigrated from backward areas of North Africa, Iraq, and Yemen. All brought with them the characteristic life habits of the lands of their origin. Jews from the Ashkenazic community are distinguished by high morbidity and mortality rates due to myocardial infarction and arteriosclerosis, but practically no cases of myocardial infarction can be found among Jews from Africa and Asia, particularly in those from Yemen. Yemenites have a low blood cholesterol level (average, 148 mg. per 100 cc.), while the Ashkenazim have an average of 231 mg. per 100 cc. In order to determine the influence of age on the lipid levels, matched controls for 25 patients with myocardial infarction were observed. The difference was statistically significant. The cholesterol level in the group with arteriosclerosis was 299 mg. per 100 cc., and the phospholipid factor was 0.915. The corresponding values in the controls were 228 and 0.746. These values were identical with those of the Ashkenazic group in the previous study, although the average age of the Ashkenazim in this study was 53, compared with 44 in the earlier study. In the order of ascending levels were newly immigrated Yemenites, Arabs, older residents of Yemenite origin, Ashkenazim, and patients with myocardial infarction. In order to discover which lipid level curves might be pathognomonic, paper electrophoretic examinations were made. In every test the protein fractions of the phospholipids were determined as well as the lipoproteins. It was found that of 52 patients suffering from myocardial infarction in the age group 35-60, only 3 showed a value of β-cholesterol above 180 mg. per 100 cc.

Another survey was carried out on 20 men who regularly perform hard physical labor and who also take a high caloric diet that is rich in fats. Only three of them had a β-cholesterol level of more than 180 mg. per 100 cc. In a group of 15 young physicians with an average age (35) less than that of the laborers, only 3 had a β-cholesterol level less than 180 mg. per 100 cc. It may thus be assumed, from the electrophoretic readings at least, that the absolute amount of cholesterol bound to the β-lipoprotein is the most important value and that 180 mg. per 100 cc. approximates the border line between those who are likely to get myocardial infarction and those who are not. Of 52 patients with myocardial infarction, 24 had a total cholesterol level below 250 mg. per 100 cc. or within the normal range. A few of them even had a low total cholesterol level (about 210 mg. per 100 cc.), but, as they had a β-cholesterol level of above 90%, their β-cholesterol level was above 180 mg. per

JAPAN

Boric Acid Poisoning: Hundreds of Babies Die.—A large number of school children were recently stricken with a form of food poisoning. The cause was traced to a certain brand of dry milk, which was found to have a high bacterial count, mainly Micrococcus pyogenes var. aureus. In the milk-processing firm it was discovered that in the middle of the evaporating process the vats were idle for 24 hours because the current was shut off due to a shortage of electricity. To counteract the bacterial havoc, the firm had used boric acid as a bacteriostatic agent. As a result, hundreds of babies died. The responsible officials were brought to trial for homicide, and many damage suits were brought against the company.

Boycott on Milk.—Recently the housewives in a city staged a boycott because of the high price of milk. As a result the price was reduced to 14 cents a quart. As yet no uniform standards exist for grading milk. Much of the milk sold in Japan is partially skimmed, and some milk is being sold sweetened with sucrose.

SWITZERLAND

Conference on Malaria.—At an interregional conference on malaria held in Athens in June under the sponsorship of the World Health Organization, it was brought out that southern Europe, from Spain to Bulgaria, has achieved remarkable progress in reducing the incidence of malaria. Before the introduction of spraying of DDT, there were about 4 million cases of malaria a year in this area, but now the figure is less than 10,000. Progress has also been made in the eastern Mediterranean countries, a reservoir of malaria throughout the ages. About 100 million of some 170 million inhabitants of this region live in malarious areas. As late as 1949, about 40 million people regularly suffered attacks of malaria. Since malaria campaigns have been extended, this figure has been reduced to about 14 million. According to Dr. Paul Russell of the United States, the solving of administrative and financial problems is the key to success in eradication of malaria. In spite of the resistance to modern insecticides manifested by some of the malaria-carrying mosquitoes, an optimistic view was taken of the possibility of eliminating the disease, because resistance to insecticides in mosquitoes is becoming better understood. Prof. G. Macdonald of London stated that resistance in mosquitoes is inherited according to Mendelian laws. Although resistance to insecticides does occur, it is not as serious as originally was feared. No definite connection has been noted as yet between the development of resistance in the mosquito and the increase in cases of malaria. In regions where DDT and other insecticides of the chlorinated hydrocarbon group have lost their efficacy, success can be achieved, although for a shorter length of time, with insecticides of the chlordane group. Before World War II there were between 1 and 2 million cases of malaria in Greece annually, but in 1952 there were only 408 cases. This has permitted an increase in agricultural activity to the point that Greece is now a rice exporter instead of an importer and wheat production has been raised to a level that is almost sufficient for the country's needs. A similar situation exists in Italy, where malaria today is practically eradicated. The number of cases has dropped from about 400,000 in 1945 to 3 new cases of local origin last year.

Since last year, Iran, Iraq, Israel, Jordan, Lebanon, and Syria have initiated programs to eradicate malaria. Total eradication has already been achieved in Cyprus, but special difficulties exist in the eastern Mediterranean region that make international cooperation imperative. One of the most important is the result of the nomadic life of millions of people whose seasonal or annual migrations, often across national borders, expose them to malaria-carrying mosquitoes. In Iran, about 23% of the population are nomads. There are many others in Pakistan, Iraq, Syria, Lebanon, Jordan, and Saudi Arabia. Studying the habits of these wandering peoples in order to be able to protect them against the disease is an arduous business for the malaria worker. The conference asked that migrations and other mass population movements such as the Mecca pilgrimage be studied with a view to malaria control. WHO is coordinating the efforts of adjacent countries that are attempting malaria eradication.

The WHO Expert Committee on Malaria believes that eradication of malaria is the only rational policy to adopt. The sums required to achieve eradication within a definite time, although substantial, are much less than the cost of continued malaria control of a less intensive character on a long-term basis. Moreover, at present several international agencies, such as United Nations International Children's Emergency Fund, United Nations Technical Assistance, and the United States International Cooperation Administration, are ready to assist governments that

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

embark on such a program. The members of the committee, pooling experience gained in such widely separated areas as Taiwan, Italy, India, and Venezuela, recognized that one of the most urgent reasons for carrying out eradication of malaria with the least possible delay was the growing resistance of the mosquito carriers of malaria to modern insecticides. Other kinds of resistance could also be foreseen, including that of the public, which, finding insecticides less and less effective against other insect pests, would object to continued spraying of their living quarters. There was also the resistance of public officials to continued annual expenditures for such spraying.

Suicide Rate.—A study published by the World Health Organization (*Epidemiol. & Vital Statist. Rep.* 9:243, 1956) states that the proportion of deaths from suicide that have not been attributed to that cause, owing to failure to recognize it or reluctance to certify a death as suicide in view of the stigma attached to this act, should be kept in mind in interpreting statistics on the suicide rate. The highest reported rates in both sexes are seen in Japan, Denmark, Austria, and Switzerland, and the lowest were seen in Ireland, Northern Ireland, Chile, Scotland, and Spain. In the United States the rate for the white population is almost three times that of the nonwhite population. Because the crude death rates are influenced by the age composition of the population as well as by the actual incidence by age and sex, the age-specific death rates for each sex, as shown in the WHO study, are better suited for comparative purposes than the crude rates. In all of the countries included in the study the suicide rate was higher for men than for women. In men the highest suicide rate occurred in those over 70 and in women in those in the fifth and sixth decades. In the United States the peak rates occurred at a younger age in the nonwhite population than in the white population.

UNITED KINGDOM

Mental Hospitals.—In the House of Commons Dr. D. Johnson stated that 20,000 persons were put into mental hospitals against their will every year; of these, 17,000 are detained on what is known as a summary reception order for periods up to a year, solely on the opinion of two or three persons empowered to sign certificates. Dr. Johnson said that mental hospitals were overcrowded to the extent of 15.6%. This would not be so if more discrimination were exercised over admissions. This could be done by establishing observation wards in general hospitals, in which patients would be away from the atmosphere of mental illness. Under these conditions a patient might recover more rapidly and without the stigma of having been a patient in a mental hospital. Figures were quoted from London County Council records to the effect that 4,746 persons were admitted to observation wards in 1955, and, of these, 1,274, or nearly 25%, were discharged after a 17-day observation period and a further 25% transferred to mental hospitals as voluntary patients rather than under an order. Dr. Johnson said that the 25% discharged would probably not have left the hospital so quickly if they had gotten entangled in the mental hospital machine.

This statement was criticized by the secretary to the Ministry of Health. The substantial increase in the number of voluntary patients from 51% in 1946 to 75% in 1955 showed that there was a new outlook. In cases of emergency there had to be prompt removal of a patient, and that was what the summary reception order was for. Before the National Health Service in 1948, these patients were sent to public-assistance institutions, then known as mental asylums. But by 1955 there were 71 mental hospitals, 43 mixed hospitals, and 26 general hospitals to which persons could be compulsorily sent, and 24,470 patients were admitted to them. Of those sent to mental hospitals 82% remained, but only 25% were certified insane. There was no lack of sympathy with these patients. Domiciliary work by local authorities had been extended so that they would obtain early psychiatric treatment.

Wage Claim by Physicians Rejected.—Medical practitioners employed under the National Health Service and hospital medical staff have advanced a claim to the Minister of Health for increased pay. This was asked for owing to the rise in the cost of living, to which salaries were geared by the Spens Committee in 1948. The Minister of Health, Mr. Turton, has rejected the claim, stating that, under the present economic circumstances, with industry being asked to freeze wages and banks to restrict credit, he was not justified in considering any increase in remuneration for physicians. According to the recommendations of the Spens Committee, accepted by the government in 1946 and 1948, the remuneration of physicians in the health service should have been increased by 24% as of April 1, 1956. Physicians were enticed into the health service in 1948 by the terms offered by the Spens Committee, which was accepted by the government. The *British Medical Journal*, in commenting on the situation, says: "The Minister should at least recognize the legal force of a contract. Doctors coming unwillingly into the N. H. S. in 1948 because Parliament, Press and people bludgeoned them into it, nevertheless thought that the people through Parliament would keep their word. The Minister and Secretary of State for Scotland . . . say they do not accept the premises on which the memorandum is based. Does this mean that they repudiate the reports of the two Spens Committees?"

The negotiating committee acting for the physicians has made the following statement: "The doctors of the country will be astonished by the flat rejection of a claim which in justice and logic cannot seriously be challenged. The medical profession have borne without complaint the steady decline in the real value of their incomes during the past five years. . . . This year the profession were at last driven to request an adjustment. The Minister's curt dismissal of that request will shock the profession, and will be regarded as a poor recognition of the restraint they have shown. The claim in no way runs counter to the recent plea by the Chancellor of the Exchequer for a halt in new wage and salary claims, for the simple reason that the claim is merely one for the implementation of a contractual obligation already in existence and which has been so since 1948."

Headquarters for College of General Practitioners.—A large sum of money has been given to the College of General Practitioners to build a new headquarters in London to serve its 3,660 members and associates in Great Britain and overseas. The gift, which is anonymous, is from a layman. At present the college has its offices in Chelsea and hold its meetings in the hall of the Society of Apothecaries. The new site will be on the south side of Lincolns Inn Fields, adjacent to the Royal College of Surgeons, which has agreed to lease the college a site. The donor's generous financial support will cover not only the cost of construction of the building but part of its maintenance. The sum involved has not been mentioned, but is probably between $300,000 and $500,000. Three houses owned by the Royal College of Surgeons will have to be demolished before the new building is erected The secretary of the College of General Practitioners, which was founded in 1952, described the building of the new headquarters as "a most important step towards the integration of British medicine and for the academic future of family doctors."

Blindness.—The Ministry of Health has issued a report on blindness in England, prepared by Prof. Arnold Sorsby (Blindness in England, 1951-1954, London, Her Majesty's Stationery Office, 1956). The major causes of blindness are the degenerative changes of old age. Cataract accounts for 26% of the total number of cases, senile macular lesions for 22%, and glaucoma for 14%. There was an increase in the total number of blind from 86,389 in 1952 to 93,622 in 1954, but practically the whole of this increase is confined to persons over 70 years old. There are more women than men among the aged blind. The commonest cause of blindness in the old is still cataract, and, although half the cases respond to treatment, 82% of those afflicted with it are not treated, chiefly because of fear or ignorance. A number of the aged also buy their glasses from the unqualified in stores, and the condition therefore often goes undiagnosed and untreated. The number of registered blind under 60 is decreasing, probably because treatment is sought more often by the younger age group. The reduced incidence of sympathetic ophthalmitis may be due to the use of cortisone. There has been a great increase in blindness in the very young, probably as a result of the increase in retrolental fibroplasia, which is the cause in over 50% of the blind children under a year old and in 25% of those aged 1 to 4 years. Now that the cause of retrolental fibroplasia is known and the oxygenation of premature babies has been drastically reduced, the disease should practically disappear.

CORRESPONDENCE

INTRABRONCHIAL BLEEDING

To the Editor:—I have read with interest an article in the June 9, 1956, issue of The Journal, page 525, entitled "Massive Hemorrhage Occuring During Bronchoscopy" by William K. Hamilton and Samuel H. Walker. Although I do not wish to indicate that any form of treatment could have guaranteed a favorable outcome in the case reported, I should like to report that I have recently successfully treated a patient with similar intrabronchial bleeding following bronchoscopic biopsy by packing the involved bronchus with a long strip of narrow gauze through the bronchoscope. It was necessary to maintain both the gauze and the bronchoscope in place for about one-half hour, during which time the bleeding ceased. The patient tolerated the procedure very well and experienced no respiratory embarrassment. Bleeding did not recur. The postoperative course was uncomplicated. This method has been successfully employed by others. I would like to suggest that it be used more often, as it is simple and effective.

CONCENTRATED ERYTHROCYTES FOR TRANSFUSION

To the Editor:—Liber and Kramer, in their article "New Method of Preparing Concentrated Erythrocytes for Transfusion" (*J. A. M. A.* 161:862 [June 30] 1956), advocate centrifuging the inverted bottle of blood, thus transferring the red blood cell layer to the outlet end of the bottle, whereby the red blood cells can be given to the patient and the remaining plasma discarded, thus eliminating the dangerous method of aspirating the supernatant plasma from an upright bottle of blood, which is in common use today. Most centrifuges are not equipped with cups large enough to hold blood bottles; hence the adapter cup described, which prevents crushing of the bottle neck during centrifugation, is not likely to find wide use. An effective method that requires no unusual equipment, mentioned but not emphasized in the authors' article, consists of storing a supply of blood of assorted types with the bottles upside down, held in any suitable rack. Two such racks can be kept in the blood bank refrigerator, each rack selected to hold as many bottles of packed blood cells as the hospital finds it needs to keep on hand. When a new shipment of blood arrives from the collecting center, the "new" rack is filled and the red blood cells allowed to settle and, when this is complete, the bottles in the "old" rack are turned right-side up and used as whole blood; the label "old" is transferred to the recently sedimented bottles, and the "new" empty case awaits the next shipment. Thus a supply of fresh red blood cells is kept available for patients who need fresh blood cells most, and waste through expiration is minimized. A separate refrigerator, to avoid jarring of the sedimented red blood cells, is desirable but not necessary.

Capt. Jesse Bryant (MC), U. S. A. F.
U. S. Air Force Hospital
Stephenville, Newfoundland.

MUMPS ORCHITIS TREATED WITH CORTISONE

To the Editor:—The most dreaded diseases associated with recruiting in armies from time immemorial have been measles and mumps. In World War II, due to the use of anti-infective drugs, the complications of measles were largely overcome, and mumps, because of its complications, became the most dreaded disease of recruits. Nothing that I have tried in the past for the relief of mumps orchitis has given the slightest benefit, except surgical relief of pressure. For that reason, I believe that the dramatic relief of pain and symptoms in mumps orchitis now achievable with cortisone should be made known. Patients with mumps rarely are hospitalized until after the orchitis has occurred, so that there is little chance for prophylaxis. In running a 500-bed mumps hospital in the military service several years ago, I found that suspending the scrotum in a well-fitting suspensory and preventing the patient from leaving his bed until all parotid swelling was gone markedly reduced the incidence of orchitis. It is a mistake to allow these patients up to go to the toilet. Estrogens were tried but were of no value. The one thing that seemed to be useful in saving these testes after orchitis had occurred was to slit the tunica vaginalis surgically and relieve the pressure that would otherwise cause atrophy. The procedure never became popular and was done too infrequently to be of real value in the approach to the problem.

About three years ago, I started adding cortisone therapy to the other supportive measures used in treating mumps orchitis. The drug was given by mouth with an initial dose of 300 mg. preferred, followed by 100 mg. every six to eight hours for two to four days. The results were dramatic. Pain disappeared in 6 to 12 hours as a rule, and the swelling was gone in two to four days. Cortisone is a valuable drug in treating mumps orchitis. Subjective relief and cessation of fever are obtained within a matter of hours, and objective relief within two to four days. It has replaced all other therapy in this hospital. Experience has shown that the initial dose should be at least 300 mg. by mouth, followed by 100 mg. at six-to-eight-hour intervals, depending on the size of the patient and the response obtained.

ROENTGENOGRAPHY FOR RETROPERITONEAL TUMORS

To the Editor:—The paper of Evans and Poker entitled "Newer Roentgenographic Techniques in the Diagnosis of Retroperitoneal Tumors" (*J. A. M. A.* 161:1128 [July 21] 1956) perpetuates a number of fallacies regarding retroperitoneal pneumography requiring clarification. 1. The presacral route of injecting gases into the retroperitoneal space has not abolished the danger of gas embolism. Although only two deaths and one severe nonfatal reaction from use of this technique have been reported thus far, we have learned of 24 additional fatalities and 33 additional severe nonfatal reactions. This information was obtained in response to a questionnaire sent to more than 1,700 urologists throughout the United States. 2. Oxygen is no safer than air as far as the danger of gas embolism is concerned. Five of the 24 deaths we have gathered occurred in cases in which oxygen was used, certainly not proportionately less than those due to air, in consideration of the relative frequency with which these gases were used. This fact was well established by Harkins and Harmon in 1934 (*Proc. Soc. Exper. Biol. & Med.* 32:178) and by many others. Helium, if anything, is more dangerous than air or oxygen. Carbon dioxide is the only really safe gas. The safety of gases is proportional to their solubility. Carbon dioxide is 20 times more soluble than oxygen at body temperature. The safety of carbon dioxide has been dramatically demonstrated recently by the work of Durant, Stauffer, and Oppenheimer of Temple University, who have injected as much as 150 cc. of carbon dioxide intravenously in one second. The gas fills the chambers of the right side of the heart and acts as a contrast medium for cardiac roentgenography, yet no sign of gas embolism follows this procedure. The results of our survey and an analysis of the 58 deaths and 64 severe nonfatal reactions due to gas embolism resulting from retroperitoneal pneumography (presacral and flank routes) are to be published shortly in the *Journal of Urology*.

MISCELLANY

This is the second part of a two-part article. The first part appeared in The Journal, *Sept. 15.*—Ed.

SOCIAL IN-SECURITY—THE TRAP AWAITING THE YOUNG M.D.

DON'T MISDIAGNOSE THIS SOCIAL DISEASE, IT'S CATCHING!

Richard C. Webster, M.D.
and
Richard J. Coffey, M.D., Brookline, Mass.

In deciding what to buy, you want to know the price or cost and you want some idea of the use or value to you of the object being purchased. When what you are buying with dollars spent by you today is a promise to pay to you or your loved ones certain amounts of money in the future, you are likely to be interested in the integrity and solidarity of the person you are giving your money to.

If you must promise to pay or "lend" your money to someone over an extended period in the future in order to get future benefits from that person, you also want to know how much your payments will be and how long you will have to keep making them. You certainly will want to know that the person your today's money is going to will be able to pay his obligations to you or your loved ones in the future. You certainly will want to know what that person's future obligations to you and your family will be. If you have any sense at all, you will not give your today's dollars to someone when the very process of giving tends to make it more difficult for him ever to repay you. If, today, he, in turn, spends the money you give him and "covers" his debt to you with I. O. U.'s written to someone else guaranteeing future payment to that person, with interest, aren't you likely to be concerned about the future return of your dollars to you and your loved ones?

Suppose the person you are giving your today's dollars to cannot be a producer of income. His only source of income is taxation. Can he ever pay you or the other person with the I. O. U. back unless he first takes in the income from you and/or the other person by increasing your taxes or those of your children?

Let us see how we can judge the wisdom and the integrity of the "system" you have been asked to pay toward. The U. S. Department of Health, Education, and Welfare, in May, 1955, put out a booklet entitled "Your Social Security" to explain Old-Age and Survivors Insurance under the social security law. We quote from it: "The schedule of tax rates given above is designed to meet the future obligations of the program and keep it on a self-supporting basis." Wouldn't you think that these words would mean that the schedule of tax rates (the one mentioned early in part 1 of this article) is now set high enough so that the social security taxes you and others pay will cover all the expenses of the social security system, including benefits already promised? As you will see later, the statement going out to the American public and just quoted by us is a downright lie or it is in error.

Many of the proponents of social security have been claiming for years that the tax rate schedule was high enough to cover the future obligations of the program and keep it on a self-supporting basis. If their claim was valid, why was the schedule revised upward in 1954? Did someone goof? Or is this all part of a master scheme to increase the power of the government at the expense of the initiative of the individual? Wouldn't you more readily accept this plan if you thought that the tax rate schedule would remain fixed at its present (or, even better, at its old) level? Wouldn't you be happier about the system if you could count on its being truly self-supporting, so that it would never dictate the need for increases in other taxes? Many other Americans have taken the words quoted at face value. Apparently, not too many have learned yet that they have been hoaxed or, at least, misled.

Only a few months after the booklet just mentioned was distributed, the House of Representatives rushed the Cooper bill through by a huge majority. Public hearings were denied. You've guessed it! This bill would further raise the schedule just a few months after it was touted to the voters as being "designed to meet the future obligations of the program." Can you make plans for your retirement or family security intelligently with this kind of performance in the background?

Words can be potent tools for good or evil. "Federal Old-Age and Survivors Insurance Trust Fund" is a title loaded with words semantically designed to create confidence and an aura of respectability. In fact, we must admit that we would never have questioned what happens to the money entrusted to the government had we not heard a representative of the Social Security Administration outline the workings of the fund. Some things he said made us a little suspicious of what the Social Security Adminstration means by the words it uses. Since then, we have taken the time to dig out some facts that indicate the enormous dangers to all Americans, not just the physicians, in the social security program.

It is absolutely necessary for you to understand that the words so glibly and repetitively used by advocates of social security have been corrupted and distorted to the extent that they have no validity as employed. We will leave it to you to decide for yourself whether those using these words in such fashions are doing so through ignorance or in a deliberate attempt to propagandize our citizens—and us—into taking actions, or allowing actions to be taken, to further their purposes.

We cannot overemphasize your need to understand that social security is not insurance! If it is insurance you have contractual rights. These are enforceable in the courts. But in social security you have nothing but statutory rights to statutory benefits. You are left completely at the mercy of Congress; for it is Congress that, at any time, can change the amounts that you must pay in taxes, the benefits that may be paid you or your loved ones, or even the classifications of those who will be paid. In fact, Congress could decide that no benefits whatsoever will be paid. Your rights under title 2 of the Social Security Act are neither natural, constitutional, nor contractual. Have you ever read in the publications of the Social Security Administration or heard in the speeches of its officials the following reservation of power (sec 1104): "The right to alter, amend, or repeal any provision of this act is hereby reserved to the Congress"? It is there and has been ever since the beginning of the act.

Once you are forced into the system, can you decide not to pay the tax because Congress votes changes you don't like in your benefits or eligibility or taxes? You cannot. This is a one-way street, pure and simple, and it does not go your way.

To understand the corruption of the term "insurance," you have to go back a bit. We quote from "Social Security After 18 Years," a report released in December, 1954, by the Committee on Ways and Means of the House of Representatives. "Insurance terms were first employed, and liberally so, in the Social Security Act when amended in 1939. The then Chairman of the Social Security Board urgently pressed for the inclusion of such terminology. The basic substance of the act, however, was not changed by the mere insertion of the word 'insurance'."

In 1937, the United States government, as defendant before the Supreme Court, stated in its brief: "The act cannot be said to constitute a plan for compulsory insurance within the accepted meaning of the term 'insurance.'" In a press conference the next day, however, the former chairman of the Social Security Board announced, "The decisions handed down yesterday by the United States Supreme Court completely validate the unemployment compensation and Federal old-age insurance provisions of the Social Security Act." Not once in its decision did the Supreme Court refer to title 2 and title 8 as "insurance"!

From that time on, "various insurance terms were liberally employed in publicizing the program under title II. And by 1939, the reverse side of the social-security cards carried by individuals referred to the title II program as 'Federal old-age insurance.'" In a press conference in 1939, the former commissioner said: "Think of it! It is just as if you had written a group insurance policy, covering 45 million people." A 1940 Social Security Board publication observed, "The tax is a sort of premium on what might be called an insurance policy."

In 1944 the former commissioner testified before a congressional committee, "The result of that [1939 amendments], as I said, was to put into effect overnight about $50 billion face value of what is really life insurance." In 1948, a former Federal Security Administrator stated, "Old-age and survivors insurance and unemployment insurance are insurance." A publication of the Social Security Administration in 1951 reads, "Treat this card like an insurance policy." Another in 1952 says, "Your card is the symbol of your insurance policy under the Federal social-security law."

A 1955 booklet scatters the following insurance terms, among others, throughout its contents for the people to read: "becoming insured," "fully insured," "currently insured," "insured status," "insurance payments," "old-age insurance benefit," "beneficiary," "spouse of an insured worker," and "insured person."

Why should the proponents of social security want the American public to think of social security as insurance? Can you think of a better way to sell a paternalistic or socialistic scheme of compulsory taxation to a traditionally independent and democratic people than to make its title and terminology synonymous in the peoples' minds with insurance, one of our oldest and most honored institutions?

That their advertising, propagandizing, or educational campaign over all these years has been successful is attested to by the following facts and quotations:

1. "Many of the letters received from people throughout the country indicate clearly that their complaints arise from their belief that the program under title II of the Social Security Act is insurance" (From the House Committee on Ways and Means 1954 report).

2. "Members of Congress have also been misled. A committee minority report stated with respect to the proposed amendments (1939): 'It puts the Government in the position of changing the terms of a contract'" (same report).

3. "Some people in labor have also been misled. For example, in a recent article in the *Machinist's Monthly Journal* (International Association of Machinists, AFL) the author stated: 'I believe that OASI is insurance and that payroll deductions are the same as premiums and, further, feel strongly that there is a definite contractural relation between the individual and the Federal Government'" (same report).

4. In the 1956 edition of the "Family Success Book" published by *Changing Times,* the Kiplinger magazine, the section on social security begins with a statement that you carry an insurance policy around in your pocket, referring to the social security card. They do qualify the statement in the substance of the article and list some of the ways that social security differs from real insurance.

5. A post card poll of the members of the Massachusetts Medical Society showed a 68% response (4,554 out of 6,693 members) as of Dec. 9, 1955. Seventy-one per cent had voted for inclusion of physicians under social security. We have talked with several hundred physicians about this subject. Almost all who wanted to have compulsory inclusion of physicians in social security thought that it would provide them with wonderfully inexpensive life insurance. Most of those we have talked with were men below age 50. The *Newsletter* (Jan. 13, 1956) distributed to the members of the Massachusetts Medical Society remarks about this preliminary poll that "it was apparent that the younger men, particularly veterans of World War II (and this includes the vast majority of our membership), were more outspoken in their desire to be included under the Social Security program than the older men." Most of the younger men we have talked with have been told about "social security insurance" in such glowing terms that they intensely resented the older physicians' opposition to inclusion in what the younger men thought was an unbeatable opportunity to get insurance.

May we pause here for one moment? Before reading this article, had you thought of social security as insurance? Did the relation of it in your mind to insurance make it more acceptable to you? If you had accepted it, had you done so because someone told you it was "cheap insurance" or "better insurance than you can buy anywhere else"? Did you have access to the figures mentioned in the first part of this article, or was your acceptance on the basis of faith in the "insurance value" you had heard or read about? If the scheme had been titled "Compulsory Taxation on Your Earnings to Allow Past, Present, and Future Payments to Some Survivors of Those Who Could or Would Not Protect Themselves and to Those Who Are Not or Will Not Be Working Beyond a Certain Age—a Method of Paying Other Present Government Expenses with What Is Left over at Present—a Device to Pay for Your Generation's Improvidence by Writing I. O. U.'s That Your Children and Their Children Must Pay"—if the plan had had that title, would you have accepted it? Yet that is what it is. If you, one of the most highly educated men in society, had swallowed it, how about those whose trainings have not taught them not to accept things on faith or hope, as yours has done—wouldn't they be "naturals" for such propaganda? Ask your next 10 or 20 patients if they know whether there are any differences between social security and insurance. Ask them what the differences are. Then ask them if they like social security. Compare the number of those who say "yes" with the number who would vote for the plan more accurately labeled with our title. Can you see why the advocates of social security would be interested in this old propaganda technique?

We can assure you that social security is not insurance. You can have no idea what your future social security taxes will be or how long you will have to pay them. How many insurance policies of any kind have you bought or heard of where your premiums or the premium-paying period can be raised against your wishes at any time by the insurance company? You have no conceivable way of determining what your social security benefits will be. Do you know of any life insurance policies where the amount of the payments to your beneficiaries or the method of deriving the amount is not spelled out by contract? Do you know of any insurance company that can change the amounts owed in the future to the policy-holders in order to please the stockholders or the management? You cannot know what changes will be made in eligibility requirements or in criteria to determine who will or will not receive benefits under social security. Do you know of any life insurance companies where management can change or eliminate the beneficiaries of your policies against your will? Under social security, a change made against your will by Congress must be acceded to by you. You can't even quit and stop paying. With insurance, you can enforce your contractual rights in court, for one thing; and you certainly can terminate your premiums and your contract when you are displeased or when it is no longer of any use to you. You can see the importance of contractual rights!

American courts have consistently held that "insurance" involves a contract. Can't you imagine the round robin you could get into trying to "insure" against breach of faith on the part of the "insurer" if there were no contracts? The federal government has established several programs, such as national service life insurance, that truly constitute insurance. The Supreme Court has held that these true government insurance contracts cannot be abrogated by Congress. This decision, delivered by Justice Brandeis, said that "war-risk policies, being contracts, are property and create vested rights." But social security is not on this list, and it certainly is not insurance! There is no contract! There are no protecting guarantees!

Now back to integrity. Since you have no contractual rights, you can only have faith in the integrity of those administering social security and those setting up its provisions. With what we have said about the corruption of words, as just one example, just how much faith in administration do you have? We will say more about this later. How much faith do you have in the present Congress? In all future Congresses to come? They legislate the provisions. Can you be sure that they are as interested in your personal welfare and that of your family as you are? In order to write laws applying to millions, can they, even in good faith to you, a physician, legislate plans that will absolve you of your peculiar responsibilities to yourself and your dependents? Can they not, in bad faith to you, legislate you, with your small number of votes, into unfavorable situations to please the larger number of less hardworking and more improvident voters? Doctor draft is an example of what they can do.

To give you an idea of the solidarity of the "institution" you are being asked to join, let us explore the workings of what is pleasantly cloaked with the name "F[illegible]ge and [illegible]vivors Insurance Trust Fund." Again [illegible]g to fi[illegible] the propaganda mills have [illegible] w[illegible] [illegible]tors' hours [illegible]

The Social Security Administration promises: "The social security taxes collected by the Internal Revenue Service are deposited in the Federal Old-Age and Survivors Insurance Trust Fund and are used to pay all the benefits and administrative expenses of the program. They may be used for no other purpose. The reserve portion of the trust fund—that is, the part not required for current disbursement—is invested in interest-bearing United States Government Securities" (From the social security booklet of May, 1955).

You hear talk about this "insurance trust fund" and how it protects you. Have you analyzed the real meaning of the words "The reserve portion of the trust fund—that is, the part not required for current disbursement—is invested in interest-bearing United States Government Securities"? This means that that portion of your today's social security tax dollar that is not immediately paid out for administrative expenses or to people already retired or collecting survivors' benefits is given by the government to the government in return for government bonds on which interest is to be paid into the "trust fund." This in turn means that the government promises to pay the government the interest and principal (redeem the bonds) in the future so that the government (social security) can pay promised benefits. When social security gives that part of your today's social security tax dollar not immediately spent by social security for today's benefits and administration to the government, what do you think happens to it? It is used for other government expenses!

Unless we plan to use the tanks and planes thus purchased to acquire other nations' wealth, there is no way that the money spent on them is going to come back to the government. Have you figured out a way to get your employees to pay you back their wages with interest? That part of your social security tax dollar going into government workers' salaries is gone—it certainly is not what many of our physician friends would call an investment. It isn't going to be earning money for them next year —or the next.

We have left out the main way the money can come back to government. Yes, by general taxation. You see the magic of social security now. Increased taxes. Unfortunately, you cannot escape the fact that the government is You!

Today, out of your right pocket you pay a lot of others who are not working and you pay for other of your "living expenses" with your social security tax dollars. To make yourself feel good, you write yourself out an I. O. U., which you put in your left pocket. Eventually you can't work and put money into your right pocket. So you reach over in your left pocket and take out the accumulated I. O. U.'s. You, who have been so interested in protecting your families before, now make a present of the I. O. U.'s to your children. You hope that they will be energetic and honest enough, and perhaps stupid enough, to take the I. O. U.'s over and put some money in your right pocket. And you hope their children will repeat the process in their turn, ad nauseum.

But if you have too large a meal before going to bed, a specter may ride in on nightmare and knock you around a bit. Suppose, some day, your children get sick of what you have done to them and tear up the I. O. U.'s?

Remember that there is only one possibility ahead if the future promises made to a noncritical public by politicians exceed our future productive capacity. The promises must be broken. Where the promises concern the economic means around which many must base their plans for family protection and their retirements, breach of faith can well be our great American tragedy.

Some ardent supporters of social security might say this is all much ado about nothing. Do you know what the promises already amount to? By 1954, the social security–accrued liability had reached the figure of 280 billion dollars. This was the amount the government would need to pay off the present social security commitments if the system were terminated and the promised benefits were paid when they fell due. The "trust fund" contains only 21 billion dollars—in I. O. U.'s from the government to the government. Which means that there is 21 billion dollars of future taxation, not counting the interest, which also can only be paid by increased taxes.

After two devastating wars, one other rather expensive one, and 20 years of the New Deal, we had managed to accumulate a government debt of 280.7 billion dollars at the end of 1955. In less than 20 years of social security, the government owed in connection with social security alone 280 + 21, or 301, billion dollars, or more of a debt than we have been able to build up in all other ways in the entire history of our country.

The interest on the national debt in 1954 was 4.6 billion dollars. The Jan. 23, 1956, issue of *Time* stated that the interest on the government debt is budgeted at 7 billion dollars.

Using the lower figure, we find that the interest on the national debt comes to about 7% of all federal expenditures. What was 7% of your total federal income tax this year? That will give you a rough idea of your payment toward the yearly interest charges on a federal debt of 280 billion dollars. What will you and your children be paying in taxes to cover the debt of the "trust fund" and the benefits already promised?

Government actuaries estimate that the Federal Old-Age and Survivors Insurance Trust Fund, under present tax collection schedules, will rise to 146.087 billion dollars by the year 2000 and to almost 500 billion by 2050, assuming demand on the fund is low. They believe it will rise to almost 63 billion dollars by 1990 if the demand is intermediate and that it will then shrink and be exhausted in 2027. If the demand is heavy, they estimate that it will be exhausted in 1995.

With Congress today romping through your and your children's future, how much do you now trust the "trust fund"? How secure do you feel about social security? Does it have the solidarity you would like in the custodian of your money? Do you think that the promise that the social security taxes collected may be used for no other purpose than the payment of benefits and the administration of the program has been or is being kept? Do you believe that the "investment" in "interest-bearing United States Government securities" is clever and cute or do you believe that it is mighty close to chicanery?

How much faith can you have in the advocates of social security? Well, for one thing, they originally promised that old age assistance would diminish as social security grew. Instead, the 1954 report of the House Committee on Ways and Means shows that old age assistance has increased by leaps and bounds And this despite the fact that social security was going to replace the need for it.

They have tried to convince you that it is "wonderfully inexpensive insurance." Not one of the three words applies Nor does "trust fund." Their record has not been one of integrity, nor have they established an institution of any solidarity.

They say that individual initiative might be stimulated if future hazards were lessened. Where does social security make any promise it can be sure of keeping? We think its very existence on such a dreadfully unsound financial and political basis constitutes one of the greatest hazards of our century.

They say private effort in the welfare field might well become less necessary if the aged were protected against penury. True, but while we are at it, let's protect everybody. Let's have a no-day work week. There are the old and the young Is it right to promise the old that from this day forward the young will keep the old from want? Do we want to encourage today's young not to try to provide for their own old age by promising them that tomorrow's young will do the job for them? Would you, an honest man, do that? And if you would, who can guarantee that someone will be around tomorrow to force your commitments down the throats of tomorrow's young?

Although many may not realize it yet, the future social war of consequence will not be between capitalist and labor, it will be between the old and the young. It is a war that to a large extent is preventable. Our generation's desire to get a "secure old age" is not designed to keep us on friendly terms with tomorrow's young

To give you an idea of what we mean, let us provide you with a few more figures. Since 1900 the population aged 65 and over has quadrupled, while the general population of the United States has doubled. In 1954 there were 13 6 million people over 65. In 1965 there will be 17.3 million. By 1980, one of every eight people will be 65 or over. Only 24% of the voters in 1900 were 50 or over, the percentage is now 37; in one generation at least 42% will be 50 or over. These people already do form a potent political block. Through their votes they can lead us into mass national dishonesty, national bankruptcy, or into a revolt of youth, overburdened by taxes inflicted on them by the old. Let "social responsibility" replace "individual responsibility" and our country's prognosis is poor indeed.

Do you know how far we have gone down this road? You, as a young physician interested in providing financial protection for your family and in putting something aside for your old age, are forced into social security. About 70 cents of each dollar you contribute goes to pay benefits of those already eligible to receive them. At the end of 1952, there were 2,644,000 persons receiving benefits. These people will receive benefits of approximately 17 billion dollars for their own contribution of a little over one-third of a billion dollars, a ratio of benefits as compared to taxes of 48 to 1. You are helping make up the difference. Total benefits to some aged couples may add up to several hundred times the amounts they paid in taxes. Yes, you are making up the difference. Today, approximately 96 to 97% of the "pension" is a gift that you and the other taxpayers are making to the oldsters. You may be willing to do this with your money, instead of putting it to your own uses; but are you willing to gamble that, with social security and other tax rates, which may be enormously high in the future, tomorrow's youth will do the same for you? If you predicate your family and personal future security on tomorrow's youth, then, the day they decide to break promises they had no part in making, you and your family have lost your security.

Doesn't this entire scheme remind you of the "chain letter" fad? For those too young to remember the details of this amusing gimmick that was so popular with the same generation that dreamed up social security, let us give you the details. You get a letter with your name at the end of a list of, say, 11 names. You are asked to send one dollar to the person whose name is first on the list. The person sending you the letter has his name next to yours at the end of the list. You are asked to send similar letters to 10 people you can trust "not to break the chain." You are not to use the name of the person to whom you sent the dollar on any of the 10 letters you send. Instead, at the end of the list, now behind your name, you put on each letter you send the name of the person to whom you send it. You are told that, "if no one breaks the chain," by the time your name comes to the top of the list, only 10 letter steps in the future, great riches await you. It is true that "if the chain were not broken" you would get 10 billion dollars.

However, a lot of people lost small amounts of money—and a few who were smart enough to get in at the beginning and who put their names early in the list got plenty of money for nothing —or for one dollar if they were "honest." The craze swept the country; pictures showing grinning parents, frolicking children, great piles of envelopes and dollar bills, and harassed postmen appeared in the papers—and then, overnight, the craze fizzled and died. People in droves were "breaking the chain." You did not see pictures of all those—in fact, we cannot remember pictures of any—who had sent in their dollars, but never got to the top of the list.

We can look back at this with tolerance and smile at the get-rich-quick mob hysteria or mass faith that produced it. We, as diagnosticians (with hindsight), can say it was just a symptom of a social disease. It certainly was not very serious, because those who got nothing in return were not hurt badly. After all, the amounts contributed by any one person were small. But we can't go along with the similar social security scheme just for laughs. The amounts involved are too large.

Let us ask those who want us to join social security how their plan differs from the chain-letter concept. Well, it involves enormous amounts of money at the beginning and the time intervals are greater. Also, with government I. O. U.'s taking the place of some of the actual dollars, we can fool ourselves into thinking the picture is rosy a while longer. However, the only real difference is that element of compulsion. You can't break the chain. Nor can your children. But can't they? Take enough of their production from them in taxes and a breaking point will be reached. And when that day comes, a lot of older hope-happy contributors are going to see their plans for security for what they were, daydreams or nightmares.

The proponents of compulsory inclusion of physicians under social security say that the taxes will not be unbearable. We say that the burden of proof is on them. We are not under social security yet; prove to us that the social security taxes will not be unbearable. Don't just predict, don't just promise, give us a guarantee that will stand up in court. Of course, they cannot do this. They glibly soothe us by saying 8% of payroll is not unbearable. We believe we have shown that their promises are—well, what would you call them? Their predictions have been anything but accurate. Their guarantees are nonexistent.

Plenty of physicians we know think their taxes are high already (Epis Taxes—they bleed you through the nose). They want tax relief, not more taxes. Our study indicates that social security taxes are going to rise, that they will rise faster than the advocates of social security will admit, that the phony "trust fund," the already promised "benefits," the politically expedient trend toward ever greater promises, and the fact that social security is not on a pay-as-you-go basis all will add up to increased taxes in our future—and our children's. Suppose we are wrong. If you predicate your inaction (staying out of social security) on our error, you will only make an error of omission. If the proponents of social security are wrong and you predicate your action (going into social security) on their error, yours will be a far more costly error of commission.

Don't think for one moment that you can buy this program piecemeal. The first step toward compulsory inclusion of all physicians would be voluntary inclusion. The only reason that we, as individuals, are out of it now is that we, as a group, are self-employed physicians and as such are not eligible. Social security history is replete with tales of groups now under compulsory coverage that started with voluntary coverage. It's like syphilis; you have it or you don't. It's like being pregnant; you are or you are not.

The advocates say that at present 7.7 million beneficiaries receive only 5.7 billion dollars in benefits each year. They say that the current social security tax can provide 8 billion dollars per year. They admit that ultimate yearly benefit payments will be higher, but go on to say that so will social security taxes, reaching 8% of payroll by 1975. Perhaps this is supposed to be an answer to soothe you. We have indicated earlier that the likely answer is anything but soothing. By 1990, the estimated costs of benefit payments will be almost 20 billion dollars. Just one year's work of Congress (Cooper bill) will raise that figure by about 5 billion dollars.

We cannot overemphasize this next statement: social security is still young; the number of people working and contributing is relatively large in proportion to those already receiving benefits. We still are in the early heyday of the chain letter. But as time passes, the number of eligible people will rise. By present figuring, in the early 1980's, the cost of benefits will exceed the income from payroll social security taxes. At this time, so say the advocates, the trust fund will level off and its earnings will fill the gap between outgo and income without any further increase in social security tax rates.

We've already given you an idea of how much you can count on their adhering to the promised social security tax rate or tax base schedules. But examine their claim that the trust fund earnings will fill the gap. The earnings they so proudly mention are from interest payments on the government securities making up the trust fund. Why sure, you pay this interest through a rise in your other taxes. You remember the right and the left pocket maneuver.

If more money is promised to the beneficiaries in the future than is taken in from them, there are just three possible courses of action open to the government. It can raise the money as it comes due by increased taxes, it can abandon the program, or it can give the beneficiaries "phony money."

Some of you have seen the post-World War I German stamps with the astronomical figures printed on them. We doubt that a German doctor, whose entire life's savings could not have bought one of these postage stamps, looks upon inflation as a good way for government to "keep the faith." To give you a quantitative idea of what the "squeeze" of increased taxation and slow inflation means, let us put at your disposal a few more figures. Take the 15-year period 1939-1954. "Taxes" include federal income jection of DPT, paralytic disease developed (within 2 weeks) in only three. The frequency with which three members of a household have been stricken with clinical poliomyelitis has been estimated by Siegel and Greenberg to be 0.2% of all households affected. This rate would undoubtedly be even lower if only paralytic cases were considered. There is some suggestion, therefore, that the DPT injections may actually have predisposed to the development of paralytic disease in the patients considered here. Severe trauma to the left arm 10 days prior to onset of paralytic symptoms may have been a further factor in the localization of paralysis in one of the patients. At any rate, paralysis of the left arm appeared first and most prominently during the first few days of illness. Another patient received DPT in the left buttock, and the left lower extremity was the only limb paralyzed. Residual paralysis in another sibling involved both lower extremities with almost total paralysis on the left, but the side of the DPT injection could not be recalled.

Although the association of antigen injection with subsequent paralytic disease was striking in three members of the family, the failure of paralytic disease to develop in two children who had also received DPT is of considerable interest. Large amounts of type-1 poliomyelitis virus were present in the stools of both nonparalyzed siblings, and, although no specimens of blood were obtained soon after injection, serums obtained later had high titers of neutralizing antibody to type-1 virus. These findings are rather good evidence that these two children were infected with poliomyelitis concurrently with their paralyzed siblings. One of the nonparalytic patients appeared to have had an abortive-type infection with minor symptoms, while another had completely inapparent infection. The fact that these two children received DPT vaccine and failed to develop paralytic illnesses suggests that recent antigen injection is not the sole or determining factor in the development of paralytic disease in persons who are harboring the poliomyelitis virus. The serial antibody studies indicate that both parents had previously been exposed to all three poliomyelitis virus types and were immune. The complement-fixing antibody response in the three paralyzed children is difficult to interpret, but is in keeping with previous studies reported on this subject. The decline or disappearance of complement-fixing antibodies after 32 weeks contrasts with the sustained high level of neutralizing antibody levels. The observations reported here give support to the practice of withholding or postponing injections of an elective nature if the patient has symptoms of a minor ailment. This would apply when there is reason to suspect that the minor ailment may represent infection with poliomyelitis. In the family cases of this report, however, the impending poliomyelitis could not be anticipated because the children were asymptomatic when DPT vaccine was given.

Acute Poisoning with Isoniazid Treated by Exchange Transfu-

B. E. Katz and M. W. Carver. Pediatrics 18:72-76 (July) [Springfield, Ill.].

[illegible] case of acute isoniazid poisoning in a 19-month-old child is [illegible]ported. Seizures and cyanosis persisted after the patient's stomach was lavaged and oxygen was administered. The patient was admitted to the hospital, where examination revealed a comatose, cyanotic, and apneic child having intermittent, generalized, tonic and clonic seizures more marked on the right than on the left side. The pulse rate varied from 80 to 104 per minute. The skin was flushed and cynanotic at intervals. The pupils were 4 mm. in diameter and responded to light. The neck was not resistant to flexion, and the cervical musculature was atonic. The heart tones were of normal quality, and no murmurs were heard. Blood pressure was 100/60 mm. Hg. The liver edge could be felt 1 cm. below the costal margin on the right side, and the tip of the spleen was palpable. Neurologically, there was a generalized hypertonia of the extremities during the periods between the seizures. The deep tendon reflexes were hyperactive. An exchange transfusion, exchanging approximately 73% of the child's blood, was performed by the method similar to that used for infants with hemolytic disease of the newborn. At the beginning of the procedure the pulse rate was 140 per minute and by the end of the procedure it had decreased to 90 per minute. By the time the exchange transfusion was completed (1 hour and 50 minutes), the child, who was breathing spontaneously and was awake, sat up on the edge of the operating table and cried for his mother.

The usual serum levels with dosages in the usual therapeutic range are 3.0 to 7.5 μgm. per milliliter. In the case presented, the amount of isoniazid ingested was approximately 83 mg. per kilogram. The serum level of isoniazid when the exchange was started was 38.6 μgm. per milliliter and at the end of the exchange 26.4 μgm. per milliliter. Eighteen hours after exchange transfusion the serum level was 7.8 μgm. per milliliter. These values may be inaccurate because of delay in their determination. However, it is possible that the dramatic improvement noted was associated with a critical level above which convulsions and respiratory depression occur and below which they disappear. The patient in this case suffered no complications and was discharged from the hospital five days after ingesting isoniazid. The pharamacological reports on isonicotinic acid hydrazide indicate that the drug is absorbed promptly from the gastrointestinal tract. Maximum concentrations may be attained in the plasma between one and six hours after administration. The procedure of exchange transfusion should be considered as a method of treatment of patients with acute drug poisoning. It would seem of special value in acute conditions in which the toxic agent is dangerous because of the effects of excessive blood level and in those in which there has been a single ingestion or exposure.

Cortisone in Treatment of Children with Chronic Asthma

M. C. S. Kennedy and D. C. Thursby-Pelham. Brit. M. J. 1:1511-1515 (June 30) 1956 [London, England].

The main object of the studies described was to assess the value of the oral administration of cortisone in improving the ventilatory function of children with chronic "wheezy" chests. A further object was to compare the effect on the ventilatory function of such children of cortisone given by mouth and epinephrine given by inhalation. Twelve children attending an asthma clinic were selected for study. All had an impaired ventilatory function as judged from the expiratory flow rate test, which was carried out as a routine twice weekly, before and after an inhalation of epinephrine. The short-acting epinephrine given by inhalation increased the expiratory flow rate of the 12 children by an average of 13% (range of 0% to 29%). During treatment with cortisone by mouth (2.5 gm. over a period of five to six weeks), the mean expiratory flow rate of the 12 children was 13% higher than during a similar course of treatment with placebo tablets. In three children the mean expiratory flow rate during treatment with cortisone was more than 20% higher than during treatment with placebo tablets. The effect of cortisone, when given at a rate of 75 mg. daily, was slow to develop, reaching a peak between the second and fourth weeks of treatment and waning when the dose level was reduced to 50 mg. daily. The expiratory flow rate increased by an average of 28% in the 12 children when the oral administration of cortisone was combined with inhalations of epinephrine. This suggests that the combined effect of the two drugs is additive. No serious side-effects were encountered during cortisone therapy over short periods. However, until more is known of the long-term effect of cortisone on the adrenals, the advisability of prolonged treatment with cortisone seems questionable.

Massive Infection with Trichuris Trichiura in a Child.

R. Gajardo and A. Atias. Rev. chil. pediat. 27:121-122 (March) 1956 (In Spanish) [Santiago, Chile].

Massive infection with Trichuris trichiura in children is rare in Chile. A 5-year-old child from a rural region of the country was normal up to the age of 4½ years, except for his habit of eating earth. At the age of 4½ years, the patient began to lose his appetite and weight and to suffer from recurrent rectal prolapse. The feces contained a large number of worms. He developed a dysenteric diarrhea, progressive anemia, and cachexia. He was brought to the hospital with symptoms of acute intestinal obstruction. He was given antibiotics and a blood transfusion prior to an operation, during which an ileocecal intussusception, three intestinal perforations, and purulent peritonitis were observed. The patient died a few hours after the operation. No other lesion that could have been the cause of death was observed at autopsy.

The number of T. trichiura organisms in the colon was enormous. The principal lesions, consisting of acute erosion and acute cystic degeneration of the intestinal mucosa, were very similar to those caused by pellagra.

OTOLARYNGOLOGY

Gout as a Cause of Respiratory Obstruction. J. B. Cavenagh and J. E. Blundell-Williams. J. Laryng. & Otol. 70:365-370 (June) 1956 [London, England].

The patient was a 75-year-old farmer whose throat suddenly became very painful. Laryngeal embarrassment increased despite various treatments. Breathing was labored and noisy and was frequently interrupted by a choking cough as the accumulation of mucus and saliva tended to spill over into his glottis and trachea, owing to his inability to swallow because of the intense pain it produced. The left side of the neck in the thyroid region was extremely tender to touch. The mucosa of the pharynx was highly injected, and mirror examination of the glottis showed injection and edema of the epiglottis, aryepiglottic fold, and arytenoid region on the left side, which completely hid the vocal cord. The patient was hospitalized, because it was feared that tracheotomy might become necessary. He was nursed in a steam tent; atropine sulfate was given to reduce the salivation. This treatment was continued for the following two days, with a gradual improvement of symptoms. The patient was now able to swallow fluids without choking, and drip infusion was discontinued. The etiology of his trouble was not clear. A request of his, however, appeared to solve the problem. He asked for gout medicine prescribed by his doctor, as an attack was starting in his left big toe. Treatment with a mixture of sodium salicylate and Colchicum resulted in rapid improvement.

One is accustomed to associate acute edema of the glottis with a streptococcic infection, trauma due to scalding or chemical agents, or possibly angioneurotic edema. Various factors in this case did not fit in with any of these categories: the sudden onset without any previous malaise or history of injury, the intense injection of pharynx and edema of larynx, and the relative lack of response to penicillin. The extreme tenderness to touch and pain on swallowing would probably have been accompanied by high fever if due to a streptococcic infection, but here the temperature never rose above 100.2 F (37.9 C) and the pulse rate never went above 90 per minute. The gradual subsidence of signs and symptoms and termination in a typical attack of gout fits in with the description of earlier writers and appears to place the etiology of this case beyond doubt. The lesson to be learned from this case and from the scanty literature on the subject seems to be that the sudden onset of pain in the throat with dysphagia, especially if intense and associated with threatened respiratory obstruction, in an elderly subject, should prompt inquiries as to a past history of gout. If this proves to be the case, antigout therapy should be started immediately.

INDUSTRIAL MEDICINE

A Study of the Effects on the Lung of Industrial Exposure to Zirconium Dust. C. E. Reed. A. M. A. Arch. Indust. Health 13:578-580 (June) 1956 [Chicago].

Pulmonary granulomatosis was observed in a chemical engineer associated with the development of the process for purification and reduction of zirconium metal after seven years of intermittent contact with this metal. This occurrence prompted an investigation into the possibility that dusts and fumes encountered in the production of zirconium might produce a pulmonary granulomatosis. The relation of zirconium to silicon in the periodic table of elements was another reason for looking on this metal with some suspicion. In the production of zirconium, compounds in dust form are encountered as zirconium chloride ($ZrCl_4$) (which hydrolyzes to zirconyl chloride [$ZrOCl_2$], zirconium oxide (ZrO_2), and metallic zirconium. In addition, workers are exposed to low and nontoxic concentration of hydrochloric acid, chlorine, phosgene, and to small amounts of other oxides and chlorides of magnesium, aluminum, titanium, and hafnium.

Studies on guinea pigs that had been placed in cages as near as possible to the heaviest concentration of dusts and that were kept in this environment constantly for from two to six months showed no evidence of inflammatory reaction, granuloma formation, or fibrosis in the lungs of any of the animals. Twenty-two workers who had been exposed to the fumes of the process of the production of zirconium for periods of from one to five years were studied. No pulmonary granulomatosis was found. None of the workers presented findings similar to those in the engineer previously mentioned. Fifteen of the 22 men had no symptoms of lung disease. Two had mild bronchial asthma. Five men had chronic cough and sputum and had consulted a physician for chest symptoms. A diagnosis of chronic bronchitis had been made, and the findings of the present investigation confirmed this diagnosis. Three of those five men worked in the chlorination room and attributed their symptoms to chlorine fumes. The subsequent course of the engineer's illness and lymph-node biopsy indicated that he had sarcoidosis or chronic beryllium poisoning (he had been rather heavily exposed to beryllium seven years previously).

A Mild Outbreak of Tuberculosis in a Large Ontario Office. H. Kinsey and H. T. McClintock. Dis. Chest. 30:77-84 (July) 1956 [Chicago].

The authors report on an outbreak of tuberculosis in a group of 1,200 office employees. A patient with far-advanced tuberculosis had been discovered in this group in December, 1952. It was established that there had been contact for 11 months, and during the following 18 months 12 additional employees were discovered to have tuberculosis. In four, no relation with the earlier cases could be established. In two of these four patients it seemed likely that exposure had occurred from known outside sources, while in two it was impossible to determine any likely source of infection. The patients ranged in age from 21 to 36 years. Seven, including the original one, were men and six were women. The first patient had far-advanced disease; those subsequently discovered included one with moderately advanced tuberculosis, seven with minimal tuberculosis, and four with pleurisy and effusion. Since no additional tuberculous infections have appeared recently, it is felt that adequate control will be provided by making chest films of all new employees promptly and of known contacts at regular intervals and by continuing the original program of mass surveys at two-year intervals.

THERAPEUTICS

Treatment of Peripheral Circulatory Disturbances with Hydrogenated Alkaloids of Ergot of Rye. R. G. Zozoya. Presse Méd. 64:1086-1087 (June 13) 1956 (In French) [Paris, France].

In 1943, Stoll and Hofmann extracted three new alkaloids from ergot of rye; their hydrogenated derivatives are dihydroergocristine, dihydroergocornine, and dihydroergokriptine. All three have an intense sympatholytic action and an important vasodilating effect. Hydergine, which is a mixture of three equal parts of these drugs, has a therapeutic action in circulatory diseases of the limbs, exercising a peripheral vasodilating effect through the intermediation of the vasomotor center and a latent adrenosympatholytic effect on the cell receptors that becomes apparent when a surcharge of adrenaline or noradrenaline is produced. Hydergine was used in treating patients with organic or functional circulatory disturbances of the limbs, such as arteriosclerosis obliterans, Buerger's disease, arterial embolism, thrombophlebitis, thromboangiitis obliterans, scalenus syndrome, and chilblains. The results obtained show that Hydergine has an intense vasodilating action, when the dosage is adapted to the individual and is carefully controlled, and a sedative effect on pain that makes the use of opiates and barbiturates unnecessary. It shortens the preoperative and postoperative course when surgical treatment is required and enhances the effect of sympathectomy. It also constitutes effective maintenance therapy and eliminates the need for repeated anesthetic blocks.

BOOK REVIEWS

Roentgen Interpretation of Fractures and Dislocations. By Joseph Levitin, M.D., Chief, Department of Radiology, Mount Zion Hospital, San Francisco, and Ben Colloff, M.D., Associate Chief, Department of Orthopedic Surgery, Mount Zion Hospital, San Francisco. Cloth. $7.75. Pp. 265, with 258 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1956.

The purpose of this book is to describe the positions that bones usually assume when they are fractured or dislocated and to tell what constitutes acceptable satisfactory reduction, whether motion can be permitted, and the status of healing. The authors have accomplished their objectives most satisfactorily by the use of line drawings rather than reproductions of roentgenograms and by the brief but adequate descriptions that accompany the diagnostic illustrations. An appendix containing bone age charts and information about common appliances used in internal fracture fixation enhances the value of the volume. The bibliography is adequate, and the index is good. This book should be of value not only to the roentgenologist and general practitioner but also to the student and resident.

Cancer: A Manual for Practitioners. Third edition. Cloth. Pp. 321. American Cancer Society (Massachusetts Division), Inc., 462 Boylston St., Boston 16, 1956.

The first edition of this book was published in 1940 at the request of the Massachusetts Department of Public Health and the American Cancer Society; a second edition appeared in 1950 under the auspices of the Massachusetts Division of the American Cancer Society. Both editions were distributed widely to physicians, medical students, public libraries, and cancer agencies. In the current edition all the chapters have been revised and several new ones added. About half of the book deals with specific organs and the remainder with general aspects of the cancer problem; specific neoplastic diseases, such as Hodgkin's disease and the leukemias; and special diagnostic and therapeutic procedures. Four chapters are devoted to cancer control activities. This compact volume endeavors to inform the general practitioner not only on the practical aspects of early diagnosis and treatment but also on the progress of cancer work generally and the broad aspects of cancer control. The authors of the various chapters are well known in their special fields and have succeeded admirably in presenting their subjects briefly and clearly. The material is well arranged and integrated. The volume does not lend itself to a review of the many controversial phases of the cancer problem. An excellent service has been performed in the preparation of this practical manual, and a significant contribution has been made to the program of cancer control.

The Drug Addict as a Patient. By Marie Nyswander, M D , Senior Supervising Psychiatrist, Post Graduate Center for Psychotherapy, New York. Cloth. $4.50. Pp. 179. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 91 Great Russell St., London, W.C.1, England, 1956.

As an outgrowth of the Harrison Narcotic Act of 1914, the drug addict has been forced into an unwanted alliance with the underworld and the physician who undertakes to treat him is in danger of losing his license to practice and of being imprisoned. The author of this forthright book not only gives a clear and concise discussion of the pharmacology of habit-forming drugs but also goes straight to the root of the problem of drug addiction. There are chapters on the physiological effects of narcotics, the psychological make-up of the addict, social pathology as related to drug addiction, and the diagnosis of addiction, with treatment and rehabilitation of the addict. The subject is of great importance to physicians, because they have been excluded from the treatment of a tragic disease and their efforts are necessary if they are to regain their logical place in the treatment of this condition. In no other country has failure to understand the problem of drug addiction led to so vicious a situation as that now found in the United States, where, if appropriate steps are not taken, matters will grow worse. An addict's glossary is given as an appendix, and an index is included. This book is highly recommended as a source of general information and because it presents a viewpoint not widely held on a subject that is almost universally misunderstood in the United States.

Foundations of Nutrition. By Clara Mae Taylor, Ph D , Professor of Nutrition, Teachers College, Columbia University, New York, Grace MacLeod, Ph.D.; and the late Mary Swartz Rose. First, second, and third editions under present title and fourth edition under title "Rose's Foundations of Nutrition." Fifth edition. Cloth. $6. Pp. 620, with 128 illustrations The Macmillan Company, 60 Fifth Ave., New York 11, 1956.

This book was first published in 1927 by Dr. Mary Swartz Rose and underwent three revisions before she died in 1941. It has now been revised by Drs. Taylor and MacLeod. Though the outline of the book has been altered very little, all the material has been brought up-to-date. The first half deals with the essentials of an adequate diet, including energy, protein, mineral elements, vitamins, and water. Chapters 19 through 24 cover contributions made by various types of food materials to the diet. Dr. Rose early introduced this approach to a study of nutrition, and as we learn more of nutrition this information becomes more and more valuable. The remainder of the book deals with adequate diets for adults, pregnant and lactating women, and children. In this discussion the unit "share" is still used in the text and is related to 100 calories of energy or $\frac{1}{30}$ of the daily allowance of each nutrient. The appendix includes extensive tables on nutritional requirements and nutritive values of foods expressed both in shares and in weights. All those who have relied on Dr. Rose's textbook for teaching and research and many others interested in nutrition will welcome this excellent revised edition.

The Structure and Function of Skin. By William Montagna. Cloth $8.80. Pp. 356, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1956.

Although the author states in his introduction that it is not possible to gather into one small volume all the information pertaining to the structure of the skin, his book comes close to accomplishing this. It does so in a manner that should interest not only the dermatologist, anatomist, and biologist but also the student and inquisitive practitioner. The presentation is that of a gifted teacher: interesting, lucid, authoritative, and orderly, showing clearly how function knits together all structures. General gross anatomy is discussed in the first chapter. The next six chapters are devoted to such structures as the epidermis, dermis, sweat glands, and pilar system. The final chapter deals more with speculative ideas than with facts. The chapter on the pilar system deserves particular notice. With the aid of pictures and diagrams, this difficult and little understood subject is clearly and ably presented. A bibliography is included at the end of each chapter, and in the introduction there is a list of standard works recommended for reference. Controversial subjects, such as the nature of the basement membrane, tonofibrils, intercellular bridges, and the origin of keratinization, are discussed fully. Although the proofreading might have been more careful, the book merits the highest recommendation.

Modern Actinotherapy: A Review of the Literature, Giving an Outline of Indications and Technique. Compiled by Raymond H Beckett, B.A With preface by Francis Bach, M.A., D.M., D.Phys.Med Cloth 17s 6d Pp. 161, with 25 illustrations. William Heinemann, Ltd., 99 Great Russell St., London, W.C.1, England, 1955.

This textbook presents as comprehensive a review of the literature on the medical use of ultraviolet light as is possible in 151 pages. However, the review of the literature is, unfortunately, not so critical as might be desired. The description of the application of ultraviolet light consists of material long known, especially to dermatologists. Much other material is included from the past regarding the application of ultraviolet light, on a rather empirical basis, in conditions that for many years have been much more effectively treated by other means and in conditions for which it is of no specific value.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

SALK VACCINE OR GAMMA GLOBULIN

To the Editor:—*If a member of a household is given a diagnosis of acute poliomyelitis, should the other members of the household (children and adults) be given the Salk vaccine at once if there has been no previous Salk immunization, or should gamma globulin be used? If the vaccine is given to unimmunized children or adults in the presence of active poliomyelitis in the household, is there likelihood of any harm being done, that is, reduction of any native resistance?*

Jackson Herbert, M.D., Portsmouth, Ohio.

Answer.—In the circumstances described, each of the preparations must be considered separately. Although gamma globulin has been used in epidemic areas with effectiveness, the consensus seems to be that it is of limited value in household members because about 90% of cases that occur in household contacts occur so soon after the index case that gamma globulin cannot be expected to be effective. This would also be true for vaccine. Others are of the opinion that gamma globulin should be used to protect the 10% in whom the incubation period after the index case is sufficiently long so that it might be effective. The time of beginning effectiveness of vaccination is longer than after gamma globulin because of the time required for development of antibody. If vaccine is given, under these circumstances, it should be considered to be for future exposure and not for the one that has just occurred. From evidence accumulated in the course of administering vaccine in the midst of epidemics, no evidence has emerged to indicate that a provocative effect has been induced.

FAMILY'S CONTACT WITH TUBERCULOUS FRIEND

To the Editor:—*A fellow physician and close friend of my family discovered within the past month that he has an open active case of early minimal tuberculosis. He has gone to the sanatorium. Tuberculin tests of myself and family are positive for my wife and me as well as for two of our children, aged 6 and 8. Our two youngest children had negative tests. Roentgenograms of all are negative. I would like to know if our children should receive treatment on the basis of a positive skin test. My wife has been a positive reactor for years, I presume, since a test done when she was in nursing was positive. I have had a patch test once or twice in the past and have always interpreted it as negative. The above skin tests done recently were intracutaneous ones with first and then second strength purified protein derivative. We are in our 30's. Can we expect our tests to remain positive?*

M.D., Oklahoma.

Answer.—Unless your two children, aged 6 and 8, have been tested with tuberculin periodically and are known to have become positive reactors recently, there probably would be no reason for administering antituberculosis drugs. The primary lesions they have apparently are too small or do not have consistency to cast visible shadows on chest *x*-ray films. Moreover, only 75% of the lung is visualized on usual films of the chest. Futhermore, 10 to 15% of lesions are extrathoracically located. Unless testing has been done periodically, there is the possibility that the two children have been infected sufficiently long that the lesions have lost their blood supply and therefore drugs administered now could not enter so as to come in contact with the tubercle bacilli. This would also apply to your wife's lesions and probably to yours, if periodic testing has not been done recently.

If the two younger children do not react to tuberculin within about eight weeks after the last contact with your fellow physician, chances are strong that they were not invaded with tubercle bacilli, since most invasions result in sensitivity of the skin to tuberculin within eight weeks. If they should be found to react at that time, antimicrobial drug administration might be considered. A number of studies are now in progress to determine whether treatment of patients whose tuberculin reaction has recently become positive with antituberculosis drugs is efficacious. If all tubercle bacilli are reached by the drugs while the lesions are still vascular and if they are destroyed, one might expect the sensitivity of the tissues to disappear. In fact, this has already been reported in a few cases, but it still is not known whether the tubercle bacilli are dead.

Evidence has accrued to show that tubercle bacilli may be so suppressed by antituberculosis drugs that for a time they cannot be grown in culture medium or guinea pigs. At first, this seemed good evidence that the organisms were dead. However, when cultures have been retained for some months, in a sizable number bacilli have begun to multiply and produce colonies. This has not occurred in all cultures, and there is still hope that in some cases all bacilli have been destroyed. There is considerable likelihood that the members of your family who now react to tuberculin will continue to do so. However, there would be no harm in retesting about once in three years, inasmuch as there is evidence that in some persons all tubercle bacilli die and sensitivity of the individual's tissue disappears. It is not yet known how frequently this occurs.

TREATMENT OF SUBACUTE BACTERIAL ENDOCARDITIS

To the Editor:—*Which penicillin preparation will give the highest and most sustained blood levels with a minimum of discomfort to a patient with subacute bacterial endocarditis? Subcutaneous administration of a soluble penicillin preparation is being considered as a better method than intravenous administration.*

M.D., California.

Answer.—Subacute bacterial endocarditis is most often caused by organisms sensitive to penicillin. However, it is absolutely imperative that a sufficient number of blood cultures be obtained prior to the initiation of treatment, so that the responsible organism will be available for identification and testing for sensitivity to all of the available antibiotic agents. This is one disease in which sensitivity testing is an absolute indication. If the organism is highly sensitive to penicillin, 1 million units of crystalline benzathine penicillin G dissolved in isotonic sodium chloride solution given intramuscularly every six hours for a minimum of four weeks is usually adequate treatment. Rarely, however, relapse may occur. Some patients with subacute bacterial endocarditis have been cured by the injection of 1 to 2 million units of procaine penicillin given in two doses per 24 hours for four weeks. Subcutaneous administration of penicillin has been used in the treatment of subacute bacterial endocarditis. Constant subcutaneous drip can be arranged by dissolving 4 million units of crystalline benzathine penicillin G (the manufacturer makes no difference—any one of the preparations passed by the U. S. Food and Drug Administration is good) in 1,000 cc. of isotonic sodium chloride solution and allowing the solution to drip through a hypodermoclysis needle inserted under the skin. A tunnel clamp is very helpful in producing a regular rate of drip.

For organisms moderately sensitive to penicillin, the dosage of the antibiotic may be increased to 10 million or more units per day. In some cases, where very high blood levels must be attained, administration of probenecid (Benemid), in a dose of 0.5 gm. every six hours, is very helpful in producing the desired concentration of drug in the blood. Most recently, cases of subacute bacterial endocarditis have been treated with penicillin given orally. This method should be used only when the responsible organisms are highly sensitive to penicillin. The drug of choice appears to be penicillin V and the dose, 1 million units every two hours; no attention need be paid to meals when this preparation is used. Some people still prefer to treat by

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

intramuscular injection of penicillin for the first two weeks, and then give penicillin V in the above dose orally for another two to four weeks. There is an increasing number of cases of subacute bacterial endocarditis due to organisms not sensitive to penicillin. Some strains are sensitive to a combination of penicillin and streptomycin; the doses of these drugs useful in these instances are 2 million units of penicillin plus 0.5 gm. of streptomycin, given intramuscularly every six hours for four to six weeks. In every instance where the causative organisms are not sensitive to penicillin, they must be examined for sensitivity to other antibiotics and the drug used to which the organisms are the most sensitive; the doses employed should be maximal and the period of therapy no less than four to six weeks.

RICINOLEATED ANTIGENS

To the Editor:—*Please inform me briefly relative to the means of preparation, the value, and the manner of administration of ricinoleated antigens.* *M.D., California.*

Answer.—The use of soaps as detoxicating agents was proposed by the late W. P. Larson, and investigations in his laboratory continued for nearly a decade, beginning in 1919. The basis for the action was the reduction of the surface tension of the medium. During this time it was reported that sodium ricinoleate was the best soap for this purpose and that, when it was used in amounts from 0.1 to 2% in final dilutions, it would detoxicate certain bacteria and certain toxins, but without impairing their antigenic properties. Thus, final dilutions of sodium ricinoleate of 0.1% would kill pneumococci and in final dilution of 0.5% would kill the streptococci of scarlet fever in about five minutes. After this destruction, no growth would ensue, but, when the micro-organisms thus treated were injected into animals, immune bodies developed. Tubercle bacilli became nonpathogenic when the culture medium was reduced to 44 dynes. It was demonstrated that tetanus and diphtheria toxins also were detoxicated by sodium ricinoleate. In an article by Larson and Eder (*J. A. M. A.* 86:998 [April 3] 1926), it was claimed that injections, ranging from L+ 0.125 to 0.25, of diphtheria toxin that had been detoxicated with a 1% solution of sodium ricinoleate would, in a single injection, produce immunity comparable to that conferred by other toxin-antitoxin mixtures of that day. These authors did not believe multiple injections enhanced the immunity produced by a single dose. The exact details of the preparation of the detoxicated solutions were never revealed, although it is evident the preparation consisted of simple mixtures of toxins and soaps. The process formed the basis of litigation some years ago, and these ricinoleated antigens never enjoyed commercial exploitation. There is no evidence that any are marketed today.

POSTPARTUM HEMORRHAGE

To the Editor:—*Does early ambulation cause postpartum hemorrhage?* *M.D., California.*

Answer.—There is no evidence at all that early ambulation causes postpartum hemorrhage. Most obstetric patients may safely be permitted out of bed the day after delivery or cesarean section. However, patients who have had hemorrhage or any other complication should be kept in bed for several days.

INFECTIOUS OBSTETRIC CASES

To the Editor:—*I would like to know the recommendations governing the care and placement of obstetric patients with infectious cases. Is there a definite ruling in writing? We have no definite section designated for infectious cases on our obstetric floor, and some laymen in our community are concerned that an obstetric infection may be transferred from the obstetric floor to another floor.* *M.D., Pennsylvania.*

Answer.—Proper provision for the isolation of the obstetric patient who develops an infection is a necessary provision in every maternity section. Such an individual is better moved out of the section of the hospital housing "clean" mothers into a private room where strict isolation procedure can be maintained. This relieves the nursing personnel in the maternity section from the added responsibility of caring for an infected mother in a clean environment. The American Committee on Maternal Welfare is in the process of establishing standards for obstetrics in which this and other problems will be considered. In many urban communities health authorities in charge of hospital regulations have developed specific rules for such problems.

BRUCELLOSIS AND BLOOD TRANSFUSIONS

To the Editor:—*In Public Health Reports, May, 1956, the following statement appears on page 511 in the article entitled "Trends in Brucellosis Control": "Although the tissues of these persons are invaded, clinical signs and symptoms arise in remarkably fewer persons than the number actually infected." To what extent do these asymptomatic cases constitute a problem in blood transfusions?* *M.D., Washington, D. C.*

Answer.—There has been no authentic instance in the United States of brucellosis being transmitted to a human being through a blood transfusion in which the donor was an asymptomatic carrier of Brucella. In the United States, most brucellosis is due to infection with Br. abortus, in which case the disease is relatively mild and the bacteremia is of a low order. However, in some areas in the world where Br. melitensis is more of a problem, the disease has apparently been transmitted through the use of blood transfusions. This is probably due in part to the fact that Br. melitensis is more highly invasive and bacteremia is more likely to occur. But even under these circumstances, the number of Brucella organisms in the blood stream is relatively small

SALT IN THE DIET

To the Editor:—*Please give information, or references, concerning the percentage of sodium in the average American diet (i. e., that added in cooking and baking).*

Frank Senska, M.D., Iowa City, Iowa

Answer.—The average daily intake of sodium of normal adults living in the United States is estimated to be from 3 to 6 gm This amount includes the sodium naturally present in foods and that which is added to foods in the form of salt and other sodium compounds (Sodium Restricted Diets, Publication 325, Division of Biology and Agriculture, National Research Council, 1954) In "Present Knowledge in Nutrition" (ed. 2, New York, the Nutrition Foundation, Inc., 1956) it is stated that the average daily intake of salt is from 10 to 15 gm. Therefore, the intake of sodium from salt added to foods would range from 4 to 6 gm

CONGENITAL ATRESIA OF EXTERNAL EAR

To the Editor:—*A 17-year-old girl has a congenital occlusion of an ear. She has never had an operation on this ear down to the eardrum. Will she lose the hearing in that ear from nonuse, or will it be all right if she has an operation in a year or two?*

G. L. Lester, M.D., Chautauqua, N. Y.

Answer.—Congenital atresia of the external auditory meatus is usually associated with a normally formed and functioning cochlea in the inner ear. Surgical correction to establish a patent meatus with creation of a substitute tympanic membrane is a satisfactory surgical procedure, which results in a partial restoration of the hearing. So far as is known, the hearing nerve does not deteriorate from disuse, so that there is no urgency about such an operation.

RUBELLA AND PREGNANCY

To the Editor:—*A patient who, according to her dates, is three months and five days pregnant from conception has rubella. What is the consensus of opinion as to the therapy for this patient, and is administration of gamma globulin of any value?* *M.D., Oklahoma*

Answer.—This patient was more than 13 weeks pregnant when she contracted rubella. This is slightly beyond the period when rubella generally affects the embryo. Since the chances of any fetal harm are slight after three months, this pregnancy may be permitted to continue. Gamma globulin should be given to the patient, because it will do her no harm and it may be helpful to the fetus.

MILITARY DEPENDENTS MEDICAL CARE

State medical societies, in preparation for their role in the new military dependent medical care program, have almost completed the first phase of their work. More than three-quarters of them have indicated they have decided on negotiating and disbursing contractors, have agreed to submit fee schedules, and have decided to set up committees that will settle medical questions and work out changes in fee schedules from time to time in the future. Of the states that already have taken action, approximately four-fifths have indicated they will do their own contract negotiating with the Defense Department for doctors in the state.

The Defense Department has announced that its next major step will be to call representatives of all participating state societies to Washington to work out individual contracts, based on a model contract that now is being formulated. There is the possibility that some of these arrangements may be handled by mail. Prior to these negotiations, however, formal implementing regulations will be drawn up and issued by the Defense Department in cooperation with the Department of Health, Education, and Welfare.

On the hospital care phase, the Defense Department is moving ahead with plans for dividing up the country between Blue Cross and commercial insurance companies, with Blue Cross getting about two-thirds of the areas. Negotiations for this part of the program will continue for several weeks. Under the law, the program is to go into effect next Dec. 8. Directing the medicare program for the Army (agent for all services) will be Major Gen. Paul I. Robinson, who presently is commanding officer at Letterman General Hospital, San Francisco. Present plans call for designating the new operation as the department's "Dependent Medical Care Division."

REHABILITATION PROGRAMS

Working toward a goal of annual rehabilitation of 200,000 persons, the federal-state rehabilitation program restored 66,273 handicapped persons to productive employment during the fiscal year ending last June 30. The U. S. Office of Vocational Rehabilitation, making public its annual report, lists the increase as 14% over the previous year. Of the total rehabilitated, about 3,500 entered such professional fields as education, medicine, and engineering; 8,200 got their training in skilled trades; and 6,200 went into the farm labor force. Others are in managerial, sales, and service jobs or in unskilled labor.

Income of the patients showed, as usual, a striking increase between prerehabilitation and postrehabilitation status. In the first full year of their employment, they are expected to earn about 119 million dollars, in contrast to the 17 million dollars earned by the same persons prior to rehabilitation. The report points out that more than 48,000 of the persons were unemployed at the time they started rehabilitation and that most of the others were in "unsafe, part-time or otherwise unsuitable jobs or were in danger of losing their jobs because of their disability." As an example of the dollar value of rehabilitation, OVR points out that about 13,000 of these people had been dependent on public assistance immediately prior to or during rehabilitation, and had been receiving approximately $11,100,000 a year in public or private aid. The total cost of rehabilitating this group was $9,200,000.

HOSPITAL DESIGN

To help stimulate more efficient hospital management, the Department of Health, Education, and Welfare has appointed an advisory committee "to study and develop methods of adapting hospital facilities and services more closely to the varying needs of patients." Heading the committee is Dr. Russell Nelson, director of Johns Hopkins Hospital, Baltimore. It will work closely with Dr. Lowell T. Coggeshall, special assistant to Secretary Folsom in health and medical matters.

In announcing the appointment of the committee, Mr. Folsom said: "Most hospitals are built and operated today to provide the maximum possible medical care involving complex and expensive equipment and personal services for each patient. Some patients, however, do not need such expensive equipment or services. If some sections of general hospitals could be designed and operated specifically to serve persons who have only limited needs, the cost of hospital care for those patients could be reduced substantially."

Among other possibilities, the committee will consider the advantages of rooms designed for patients who will be hospitalized only at night or only in the daytime, or for limited hours. Such accommodations would meet the requirements of persons whose chief need is for diagnostic services, or others who can obtain adequate care in their own homes part of the time. Many persons who need only part-time hospitalization pay for 24-hour care, because few hospitals offer part-time treatment. Another possibility is a hospital so arranged and managed that many patients can go to a central cafeteria or dining room for their meals, thereby reducing cost of food distribution. Also, patients might do some of the light housekeeping in their rooms.

Federal grant money already is available fo
perimental construction along lines that
suggested by the committee. To assist

tailed information on what has been done to date in developing or operating facilities more closely related to actual patient needs. Councils of the American Hospital Association and the American Institute of Architects, which have had these problems under study for years, will be asked to assist the committee. "The cost of hospital care has been increasing steadily," Secretary Folsom said in outlining the committee's task. "We do not expect, of course, that the work of any one committee or group in any one field will solve the whole complex problem. But we believe this committee can make an important contribution, and I am grateful to the distinguished men and women who have agreed to serve."

PHS ADVISORY COMMITTEE

A 12-man advisory committee to aid the Public Health Service in administering the three-year, 90 million dollar grants program for building of health research facilities has been appointed by Secretary Folsom of the Department of Health, Education, and Welfare. The group is to be known as the National Advisory Council on Health Research Facilities. The law provides for matching grants to institutions doing research in medicine, osteopathy, dentistry, public health, and related sciences.

The council is made up of eight members from the professions and four from the general public. PHS Surgeon General Leroy Burney and an official of the National Science Foundation are ex-officio members, with the surgeon general serving as chairman. Council members are Dr. George N. Aagaard, professor of medicine and dean of the School of Medicine, University of Washington; Eugene N. Beesley, president, Eli Lilly & Company; Dr. Thomas H. Hunter, dean of the School of Medicine, University of Virginia; Dr. Carlyle Jacobsen, executive dean for medical education, State University of New York; Dr. Paul C. Kitchin, professor of dental histology and embryology of the School of Dentistry, Ohio State University; Dr. Oliver H. Lowry, dean of the School of Medicine, Washington University, St. Louis; Dr. Robert A. Moore, vice-chancellor, University of Pittsburgh; F. C. Sowell, vice-president and general manager of radio station WLAC, Nashville, Tenn.; Dr. John E. W. Sterling, president of Stanford University; Dr. Thomas B. Turner, professor of microbiology of the School of Hygiene and Public Health, Johns Hopkins University; Dr. James W. Wilson, professor and chairman of the department of biology, Brown University; and James Bradshaw Mintener, who is resigning as assistant secretary of HEW.

PERSONNEL

The new chief of the physical medicine service at Walter Reed Army hospital is Lieut. Col. Aniello F. Mastellone, who succeeds Col. Harold B. Luscombe, retired. Col. Mastellone's most recent post was chief of the physical medicine service at Fitzsimons Army Hospital in Denver. . . . G. Cullen Thomas of Minneapolis has been named as a special consultant to the Food and Drug Administration, to serve in the area of industry cooperation and education. Mr. Thomas has retired after 26 years as a vice-president of General Mills, Inc. . . . Dr. Lewis H. Hoyle has been appointed medical director of the Kansas City regional office of the Department of Health, Education, and Welfare. As hospital and medical facilities director in the same office, Dr. Hoyle was responsible for regional supervision of the Hill-Burton hospital construction program. Dr. Charles F. Blankenship, currently the Kansas City director, moves to the San Francisco office in the same capacity. The shifts are effective Oct. 1. . . . Four new members have been appointed to the Veterans Administration special medical advisory group. They are Dr. Charles D. Shields, Georgetown University, replacing Dr. Donald A. Covalt, Bellevue Medical Center; Dr. Howard P. Rome, Mayo Clinic, who replaces Dr. David A. Boyd Jr.; Dr. Shields Warren of New England Deaconess Hospital, Boston, who replaces Dr. Robert A. Moore, University of Pittsburgh; and Mrs. Marion Sheahan Bailey, associate general director of the National League for Nursing, Inc., who replaces Mrs. Elmira B. Wickenden of Bronxville, N. Y. Mrs. Wickenden is resigning because of other pressing commitments; others are leaving the group on the expiration of their terms.

MISCELLANY

The Public Health Service has announced the awarding of 12 grants for research in various aspects of air pollution. Six are for new projects and six for continuing support of projects already under way. They amount to $318,568 and bring the total number of grants since July, 1955, to 32. The largest single grant this time was $94,340 for a continuing project—the design and organization of a study to relate the *incidence, prevalence, and prognosis* of human disease to air pollution in an urban area. . . . The Navy reports that 184 ensign (medical) officers participated in summer "cruises" at 16 naval teaching hospitals and 9 naval medical research activities during the past season. This training is part of a naval reserve program to afford qualified medical students an opportunity to join the reserve as commissioned officers while still in medical school. . . . A special course for nurses has been sponsored by the Federal Civil Defense Administration. Directed by the FCDA health office, the course included discussion of principles of civil defense and the organization, administration, and operation of civil defense programs. . . . The Atomic Energy Commission has a limited supply of spent fuel elements from its materials testing reactor for rental to licensed users. The elements are used as sources of gamma radiation employed in medical and industrial research. AEC is making a flat charge of $100 a year for use of each fuel element. . . . In preparation for National Employ the Physically Handicapped Week (Oct. 7-13), the U. S. Chamber of Commerce urges employers to recognize that physical fitness is a relative thing and must be judged in relation to a specific job. . . . The National Science Foundation, in a report titled Federal Support for Science Students in Higher Education, estimates that in 1954 the federal government aided more than one out of every five graduate students and one out of every six undergraduates in all fields of study.

THE NEED FOR COMPLETE COOPERATION BETWEEN SURGEON AND ANESTHESIOLOGIST

Warren H. Cole, M.D.
and
Max Sadove, M.D., Chicago

- *Surgeons and anesthesiologists must work together in the operative care of the patient; the abundance of new apparatus, materials, and methods that have become available to them in recent years can be fully utilized only by combining their individual resources. Increased knowledge of physiology and pharmacology has brought increased opportunities and responsibilities; these demand an extent of knowledge that can hardly be supplied by one person. Surgeon and anesthesiologist should consult preoperatively; they should exchange information as to the type of operation planned and the kind of anesthesia to be used. During the operation there must be not only a predetermined division of responsibilities but also an exchange of information as to the condition of the patient and the progress of the surgery. The danger of such complications as shock and cardiac arrest can be reduced by attention to the position of the patient, to pulse and blood pressure, to the sometimes inevitable changes in the surgeon's plans, and to the orders for postoperative care.*

We wish to call attention to the need for the maximum cooperation between the anesthesiologist and surgeon in the operative care of a patient. This close relationship is necessary if the patient is to receive the maximum benefit of medical knowledge, and we must realize that the welfare of the patient is paramount. By tradition, medicine is a service profession, devoted to treatment of the patient and his disease. We have made so much progress in our profession during the past several decades that it is not possible for one man to possess more than a small fraction of that knowledge. This fact alone is sufficient to justify the demand for efficient teamwork between the anesthesiologist and surgeon.

The rapid progress made by medicine during the past few decades has made it essential that the physician be well informed if he is going to give the benefit of this knowledge to the patient. This obligation naturally applies to the anesthesiologist and surgeon, both of whom have done their share in the achievement of this progress. The improvement in our knowledge of the need for blood, fluids, and electrolytes before, during, and after major operations has allowed the surgeon to increase the extent of the operation very much indeed. However, safety in this increase in extent of the operation has been made possible only by advances in anesthesiology; in fact, in certain fields such as thoracic surgery, the advance in anesthesiology had to precede the progress of surgery.

This need for greater knowledge is very diversified and by no means limited to one or two phases of medicine. The anesthesiologist and surgeon alike must have extended knowledge in such fields as physiology, pharmacology, biochemistry, pathology, and internal medicine if they are to utilize the progress made during the past few decades. In other words, a physician has shirked his duty if he does not keep up with major advances in fields of medicine other than his own. We must admit, of course, that many problems will present themselves in which the combined training of the surgeon and anesthesiologist is not sufficient to meet the situation. They must know how and when to ask for aid from their medical friends.

New Responsibilities of Anesthesiologist

During the past several years, the responsibilities of the anesthesiologist have changed considerably. Originally, his only obligation was to "pour ether." His increased knowledge of such subjects as physiology and pharmacology has earned him the privilege or responsibility of doing many additional things, as, for example, assisting in determining the operability of the patient and the choice of anesthetic and advising in the diagnosis and treatment of shock. Before any deci-

Read before the Section on Anesthesiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

sion can be made regarding operability of the patient or choice of anesthetics, the anesthesiologist must see and examine the patient. This is best done several days before the operation and again the night before the operation, at which time the anesthesiologist should write the preoperative orders. At this time, he should talk to the patient about the anesthetic. Often, the patient may have a fear of a general anesthetic and may urgently request a local; almost as often, the reverse will be true and the patient will insist on being asleep during the operation. If a local anesthetic is requested, the anesthesiologist will have to consult the surgeon to be sure that the extent of the operation or other similar factors will not make use of a local anesthetic impractical.

With his increasing acquisition of medical knowledge, the anesthesiologist must not forget that the practice of medicine exists for the welfare of the patient. Surgeon and anesthesiologist alike must do their best to alleviate the patient's fear, and they should order sedatives as indicated. Perhaps the most important time in this respect is during the preoperative visit and when the anesthetization is being started. A friendly, sympathetic attitude and assurance that the procedure is safe will do much indeed to ease the patient's mind. Gentleness is not only indicated but required at all times, including the period after loss of consciousness. Too often, indeed, the anesthesiologist and surgeon discard caution and gentleness after the anesthetic has taken effect. Manipulation in the mouth and harynx must be carried out gently, because the muosa is not as tough as skin. With very few exceptions, bleeding from the mouth, even if slight, is inexcusable. The manipulation most apt to cause trauma and bleeding is insertion of an intratracheal tube. The anesthesiologist must learn to do this gently; too often, postoperative hoarseness, soreness, and pain are due to roughness during intubation. If intubation is not accomplished within a few minutes, a senior anesthesiologist should be called to perform this manipulation. If the senior anesthesiologist is the one having difficulty, perhaps it is safer to change the technique or even to postpone the operation.

The increase in major responsibilities of the anesthesiologist must not blind him to some of the minor ones. For example, the controls for changing the position of the operating table are placed at the head of most modern tables, so that the anesthesiologist can reach them. It is to be hoped that the anesthesiologist will possess a cooperative spirit that will prompt him to do what he can to add efficiency to the operation.

Special Training for Anesthesiologist

Reference has already been made to the fact that the modern anesthesiologist has been forced to acquire a varied amount of knowledge to carry out his functions properly and efficiently. Actually, there are no limits on the knowledge to be possessed; the more he possesses, the more useful he will be in the surgical team, of which he is an important member. Perhaps the best example of a special area in which knowledge is required of the modern anesthesiologist is pharmacology. There are so many anesthetic agents in use today that familiarity with these alone would require a fair knowledge of pharmacology. However, the complexity of anesthesia in poor-risk patients with complicating diseases makes it essential that the anesthesiologist possess a fair knowledge of the use of all important drugs. This is particularly important when complications relating to anesthetization develop, because they so often appear suddenly and, if not corrected immediately, may lead to death.

Since an average knowledge of pharmacology is required of the anesthesiologist, it is natural that the surgeon should rely upon him for advice and consultation concerning conditions requiring drug therapy as related to the operation. This shift in responsibility is very appropriate, because it will eliminate the waste of time incurred by both if the surgeon must also be a pharmacologist. It is indicated and appropriate that the surgeon spend this time saved in learning to correct some of the important threats to safe surgery, such as malnutrition in the aged, so commonly seen by the surgeon today. The fact should be emphasized that possession of a good knowledge of pharmacology is not possible without a fair knowledge of physiology and chemistry. Accordingly, the anesthesiologist must be well informed concerning normal and abnormal physiology. In fact, it can be said without question that the skill and ability of an anesthesiologist are strongly related to his knowledge of physiology, pharmacology, and chemistry, assuming he has had good training in the techniques of anesthesiology itself.

Another requirement of the modern anesthesiologist is that he have dexterous hands and fingers. Training in insertion of intratracheal tubes, of Levin tubes during the operation, and of intravenous needles is essential. Proficiency in the former two is rarely acquired during the residency, just as proficiency in performing difficult operations is rarely acquired in the few years of residency in surgery. There are numerous other prerequisites of training or knowledge to be possessed by the anesthesiologist, but those mentioned above may perhaps be considered the most important. In fact, the anesthesiologist must have sufficient knowledge and ability to command the respect of the surgeon. If he does not, the surgeon will be distracted during the operation because of apprehension concerning the anesthetization; at times, this apprehension may be sufficient to jeopardize the surgeon's technique even to the point where he may commit serious technical errors. Furthermore, lack of respect may result in the issuance of orders by the surgeon on matters in which he is too inadequately informed to reason intelligently.

Determination of Operability and Type of Anesthetic

Although we all are striving to obtain enough knowledge and experience to make decisions regarding operability so accurately that we will have no postoperative fatalities, that utopian period is far in the distance. Yet we must admit that proper application of present knowledge will continue to reduce mortality rates. Since life is the most precious thing on earth, it is obvious that all possible knowledge must be put to work on such important problems as determination of operability in a poor-risk patient who requires a serious prolonged major operation. Under such circumstances, the combined knowledge of the surgeon and anesthesiologist must be utilized. A good example of the necessity of a cooperative study and decision is the problem presented by an elderly patient with a cancer in the gastrointestinal tract who also has a serious emphysema and perhaps mild bronchiectasis. If the anesthesiologist feels that the condition of the patient will not safely permit the operation planned, he should so inform the surgeon. Perhaps a different operative technique should be utilized.

When the surgeon possesses vital information that may not be obvious to one making a single examination, he must inform the anesthesiologist, as of a case of malnutrition proved by history of inadequate caloric intake but not detected by chemistry, which reveals normal protein levels. It is the surgeon's responsibility to recognize this deficit and correct it before operation if at all possible; unfortunately, this is not always possible, because the gastrointestinal disease may be producing a partial obstruction or symptoms such as diarrhea, which cannot be corrected. Accordingly, we wish to emphasize the importance of free interchange of questions and information between the anesthesiologist and surgeon in the preoperative period, particularly in patients whose operability is doubtful.

During the Operation

During the operation, it is essential that teamwork and cooperation be practiced to the maximum degree, because so many events that take place at this time are vital to good results or to survival of the patient. The surgeon should be informed when a significant change in the patient's condition takes place. It is a shock to the nervous system of the calmest of surgeons to have the anesthesiologist announce that the blood pressure is now 70/60 mm. Hg and that it has been falling steadily for the past 15 minutes. In fact, it is appreciated by most surgeons if the anesthesiologist announces the blood pressure and pulse every 10 or 15 minutes, even though they are entirely normal. Likewise, the surgeon should inform the anesthesiologist when any complications develop during the operation, and he should also inform him if additional work, beyond that expected, must be done. If, during a celiotomy, the surgeon finds it necessary to open the chest, the anesthesiologist should be informed as soon as the decision is made. During a thoracic operation, the surgeon must expect the anesthesiologist to request the privilege of aerating the lung on the side of the operation every 15 to 30 minutes. If the surgeon is doing something at this moment that cannot be interrupted, he should request three or four minutes to complete it and should then stop the operation for aeration of the lung.

The question concerning the need for fluids and blood during the operation is a very important one, because it comes up in all major operations. In general, this should be considered to be the surgeon's responsibility, but the anesthesiologist should keep this point in mind at all times, and, if the fluid or blood is not being given in amounts consistent with the indications from his standpoint, he should bring the question up for discussion. The decision regarding the time to start administration of blood is more important than the problem of fluid intake. If there is any question about the advisability of starting blood transfusion, it can usually be settled readily by having the nurses count sponges and by checking the amount of blood in such places as in the suction bottle or on drapes. Specific information may be available from blood-volume determinations done with radioactive albumin, particularly if preoperative determinations have been carried out. The anesthesiologist should consider it his privilege to request more blood or less blood; it is very possible that his decision may be more accurate than the surgeon's, but the surgeon should not hide behind this cloak and blame the anesthesiologist for all errors in fluid replacement.

Now and then there will be changes in the cardiac mechanism that may suggest a coronary thrombosis, and an electrocardiogram may be indicated. Since the decision regarding cardiac reserve on the operating table would appear definitely to be for the anesthesiologist to make, it would seem that he must be capable of reading electrocardiographic tracings. During the development of anesthesiology over the past few decades, numerous items of equipment have been added to the anesthesiologist's armamentarium. However, we must emphasize the fact that the anesthesiologist's ability is by no means rated according to the amount of equipment he possesses. Actually, the pendulum has swung so far toward a large amount of equipment that the anesthesiologist should be urged to limit its use; simplicity in instruments and equipment will result in better anesthesiology.

Cardiac Arrest.—Cardiac arrest is becoming so frequent and is of such grave importance that we choose to discuss it separately. Although the assignment of duties to the anesthesiologist and surgeon may vary in different hospitals, no one should question that it is the anesthesiologist's responsibility to keep track of the pulse beat, and it is his responsibility to inform the surgeon as soon as he suspects that cardiac arrest has occurred. When the operation is being performed on the heart or in the immediate neighborhood, the responsibility belongs to the surgeon. The surgeon can and should try to confirm the presence or absence of a heartbeat; if he is working in the thorax or abdomen he can readily do so. Since the time lapse between cardiac stoppage and start should not be over three minutes, someone must act as timekeeper. Unless the anesthesiologist is positive he felt a heartbeat only a few seconds previously, there should be no delay for "timekeeping," and an incision must immediately be made in the thorax by the surgeon and cardiac massage instituted. It should also be the responsibility of the anesthesiologist to order the drug therapy. It should be the surgeon's responsibility to look for ventricular fibrillation if the heart does not resume its beat, because he is the person who is best able to observe fibrillation. Every operating room should have a defibrillator available, and the surgeon in charge of the operating room or service should be responsible for obtaining one.

The Postoperative Period

There will perhaps be more difficulty in assigning responsibility in the postoperative phase of the patient's care than in any other period. Each hospital will have to devise its own formula. In general, the surgeon is responsible for the patient's welfare postoperatively, but certain duties should be as [illegible] to the anesthesiologist. Actually, here is ano [illegible] re team-

sion can be made regarding operability of the patient or choice of anesthetics, the anesthesiologist must see and examine the patient. This is best done several days before the operation and again the night before the operation, at which time the anesthesiologist should write the preoperative orders. At this time, he should talk to the patient about the anesthetic. Often, the p
tient may have a fear of a general anesthetic
urgently request a local: almost

With his increasing acquisitio
edge, the anesthesiologist must
practice of medicine exists for the
tient. Surgeon and anesthesiologist al
best to alleviate the patient's fear, a
order sedatives as indicated. Perhaps th
tant time in this respect is during the preo
and when the anesthetization is being starte
ly, sympathetic attitude and assurance that
cedure is safe will do much indeed to ease the p
mind. Gentleness is not only indicated but req
at all times, including the period after loss of c
sciousness. Too often, indeed, the anesthesiologist an
surgeon discard caution and gentleness after the anesthetic has taken effect. Manipulation in the mouth and pharynx must be carried out gently, because the mucosa is not as tough as skin. With very few exceptions, bleeding from the mouth, even if slight, is inexcusable. The manipulation most apt to cause trauma and bleeding is insertion of an intratracheal tube. The anesthesiologist must learn to do this gently; too often, postoperative hoarseness, soreness, and pain are due to roughness during intubation. If intubation is not accomplished within a few minutes, a senior anesthesiologist should be called to perform this manipulation. If the senior anesthesiologist is the one having difficulty, perhaps it is safer to change the technique or even to postpone the operation.

The increase in major responsibilities of the anesthesiologist must not blind him to some of the minor ones. For example, the controls for changing the position of the operating table are placed at the head of most modern tables, so that the anesthesiologist can reach them. It is to be hoped that the anesthesiologist will possess a cooperative spirit that will prompt him to do what he can to add efficiency to the operation.

Special Training for Anesthesiologist

Reference has already been made to the fact that the modern anesthesiologist has been forced to acquire a varied amount of knowledge to carry out his functions properly and efficiently. Actually, there are no limits on the knowledge to be possessed; the more he possesses, the more useful he will be in the surgical team, of which he is an important member. Perhaps the best example of a special area in which knowledge is required of the modern anesthesiologist is pharmacology. There are so many anesthetic agents in use today that familiarity with these alone would require a fair knowledge of pharmacology. However, the

Determination of Operability and Ty

Although we all are striving to
knowledge and experience to make decisi
operability so accurately that we will h
operative fatalities, that utopian period is
distance. Yet we must admit that proper ap
of present knowledge will continue to reduce mo
rates. Since life is the most precious thing on ea
is obvious that all possible knowledge must be put
work on such important problems as determination of
operability in a poor-risk patient who requires a serious
prolonged major operation. Under such circumstances,
the combined knowledge of the surgeon and anesthesiologist must be utilized. A good example of the necessity of a cooperative study and decision is the problem

the country that the responsibilities of the surgeon and anesthesiologist cannot be defined dogmatically. Many of these fuctions will have to be worked out according to circumstances; however, certain of them are rather obvious. For example, the surgeon and anesthesiologist should consult preoperatively, and, after the anesthesiologist has had opportunity to examine the patient and his chart, the surgeon should inform the anesthesiologist of the type of operation planned and the anesthesiologist should inform the surgeon of the type of anesthetic he contemplates using. The anesthesiologist should inform the surgeon promptly of any change in the patient's condition during the operation. Likewise, the surgeon should inform the anesthesiologist immediately of any change in the operative plan. The surgeon expects the anesthesiologist to keep constant watch over the patient's condition, and the anesthesiologist expects the surgeon to perform the operation with the least amount of trauma and minimal blood loss. The operation is no place for prejudice or anger. We must remember at all times that the welfare of the patient is the paramount issue during an operation. Complete cooperation will result in maximal efficiency.

1853 W. Polk St. (12) (Dr. Cole).

THE ROLE OF HYPNOSIS IN ANESTHESIOLOGY

Milton J. Marmer, M.D., Beverly Hills, Calif.

• *Thoracotomy and resection of the lingula pulmonis was accomplished with the aid of hypnosis in a 25-year-old woman who had previously undergone a diagnostic bronchoscopy under hypnosis. The patient was hypnotized the night before the operation and again at 10 a. m. on the day of the operation. The medication required before and during the operation included 100 mg. of pentobarbital and 50 mg. of diphenhydramine hydrochloride by mouth, 100 mg. of meperidine hydrochloride and 0.40 mg. of scopolamine hypodermically, 50 mg. of thiamylal sodium intravenously to stop involuntary swallowing, 25 cc. of 1% solution of procaine hydrochloride infiltrated into the skin before the incision, and a total of 100 mg. of succinylcholine administered as 0.1% solution by intravenous drip over a period of 45 minutes to permit control of the respiration.*

Hypnosis can be a valuable addition to the armamentarium of the anesthesiologist. It is unfortunate that the application of the principles of this technique has been almost neglected in the present-day practice of anesthesiology. Instruction in the principles of hypnosis should be incorporated into the training in anesthesiology. In fact, every anesthesiologist should also be a hypnotist. Words have long been recognized as exerting a tremendous influence on human behavior.[1] As Rudyard Kipling once said, "Words are the most powerful drug used by mankind." Hypnotism, which paved the way for the acceptance of ether and chloroform by drawing attention to the possibility of surgery without pain, was dealt its death blow by the advent of these anesthetic agents. Crawford Long,[1A] in his first published account of the use of sulfuric ether, by inhalation, as an anesthetic in surgical operations, wrote:

> At the time I was experimenting with ether there were physicians high in authority, and of just distinguished character, who were advocates of mesmerism and recommended the induction of the mesmeric state as adequate to prevent pain in surgical operations. Nothwithstanding, thus sanctioned I was an unbeliever in the science, and of the opinion that if the mesmeric state could be produced at all, it was only on those with strong imaginations and weak minds and was to be ascribed solely to the workings of the patient's imagination. Entertaining this opinion, I was the more particular in my experiments in etherization.

In 1846, Robert Liston, the British surgeon, while performing the first operation in England with ether as an anesthetic, made the classic remark: "This Yankee dodge beats mesmerism all hollow!"[2] By 1860, mesmerism and surgery had parted company. The more chemical anesthesia increased in efficiency, the less significant hypnotism became as a means of anesthesia. At the end of the 19th century in England there was a revival of interest in hypnotism, and it was again demonstrated that surgical procedures could be performed with the patient in the mesmeric state.

Hypnotic phenomena have been observed since Biblical times, but scientific and medical interest in the subject was first aroused in the latter part of the 18th century, by Anton Mesmer. He claimed to be able to cure disease by means of "animal magnetism," which he believed to be some kind of magnetic influence that flowed from him to the patient, a concept since thoroughly discredited. James Braid, a Manchester surgeon, rejected the theory of animal magnetism and attributed the phenomenon of mesmerism to suggestion. He introduced the term hypnotism in 1843.

The first attempts to perform surgery while the patient was under hypnosis were made in France, by Dupotet and Recamier, in 1821. Jules Cloquet, in 1829, removed a breast while the patient was in a mesmeric sleep. By 1837, John Elliotson had established an enviable reputation as one of the ablest surgeons in London. He performed many operations with the patients under hypnosis, but he was finally asked to resign his post because of alleged charlatanism. In 1843, he began publication of *The Zoist*, which was called "A Journal of Cerebral Physiology and Mesmerism and Their Applications to Human Welfare." According to Elliotson, the first surgical procedure carried out on a mesmerized patient in England was the insertion of a seton in the neck in 1838. Four years later, in 1842, a surgeon named Ward performed a midthigh amputation on a patient in the mesmeric state. The third volume of *The Zoist* (March, 1845–January, 1846) contained three

reports of surgical operations performed with the patient under mesmeric anesthesia, four of which were carried out in the United States. James Esdaile, in India, between 1844 and 1859, performed a remarkable series of operations on patients who had been hypnotized. The significance of his accomplishment in the use of mesmerism for surgical anesthesia is manifested by the fact that he reported on several thousand operations, of which some 300 were major procedures, including amputations, repair of hydroceles, and removal of scrotal tumors and cataracts.

Although in the past 10 years new interest in the use of hypnosis has become evident, anesthesiologists as a rule are still more comfortable when they use drugs than when they employ the less familiar psychological techniques.[3] However, if physicians understood more clearly what hypnosis is and what can be expected of it, I believe that it would be utilized much more widely and effectively. It is the only means of anesthesia that carries no danger for the patient. Hypnotism raises the patient's threshold to pain. Actually, perfect anesthesia should be attained by employing hypnotism in conjunction with chemical agents. Hypnosis can be a pleasant experience, involving no tension or apprehension. It can be maintained for long periods and terminated at will, and it has the superlative advantage of placing no extra load on the circulatory, respiratory, hepatic, or renal systems.[4]

Induction and Effects of Hypnosis

There are as many ways of producing hypnosis and as many ideas to explain its nature as there are hypnotists, but most authorities favor the theory that the mesmeric state is a condition of "exaggerated suggestibility."[5] The hypnotist has neither an esoteric power nor a mysterious gift. Anyone can learn to hypnotize, but use of the technique should be restricted to trained and competent practitioners. Patients vary in their susceptibility to hypnosis in the same way that they differ in their responses to drugs or other medical therapy. The best hypnotic subjects are ordinary, normal people, the more intelligent and imaginative the better. It is virtually impossible to hypnotize an idiot. Children usually make good subjects because of their heightened powers of imagination. Young people respond better than old, because their patterns of reaction are not so rigidly set. There is no difference in susceptibility to hypnosis between men and women.

Optimum results may not be obtained with the first attempt. Some patients who can be influenced only slightly at first can be trained to become good subjects by repeated sessions with the therapist. Hypnosis obeys the laws that govern conditioning in general. It is of the utmost importance that the patient believe that the hypnotizing physician has both competence and integrity. Pain can be reduced or obliterated in many people by hypnotic suggestion. It is well known that distraction of attention may exclude from consciousness many sensations, including pain. Pain, which is perceived, is subjective and individual; it varies in accordance with the emotional and physical make-up of the patient. Under hypnosis, the patient is conscious of pain, but his higher centers ignore it.

In the hypnotic state the subject appears to be anxious to please the hypnotist and will usually carry out his suggestions. No patient will carry out a suggestion that conflicts with his basic moral principles. The subject is not an automaton; he may refuse to carry out suggestions, and he can always break the trance if the situation becomes really intolerable. Such muscular phenomena as alterations in tone are to be expected. Catalepsy may be brought about, and any muscular activity can be increased, decreased, or completely inhibited. However, vital functions are not affected. Either analgesia or anesthesia may be produced. Partial amnesia is encountered in the majority of cases, and complete amnesia is not infrequent.

Hypnosis can be used to assist a patient to relax and to help obviate excitement and apprehension. Most people fear anesthesia more than surgery. Induction of anesthesia should start not in the operating room but with the preanesthetic visit to the patient, usually one or two nights prior to surgery. Many emotional changes accompany anesthesia, and it is well known that stress may produce hypertension, tachycardia, or irregularities of cardiac rhythm. Although every person handles anxiety in his own fashion, the correct psychological approach on the part of the anesthesiologist will go a long way toward obtunding psychic trauma and establishing confidence.

With most patients I have used what I call "an exercise in relaxation" as a trial attempt at hypnosis. If, during the relaxing exercise, the patient follows suggestions and a hypnoid level is approached, more suggestions are made, in the hope that a deeper level of hypnosis will be achieved. Even when it is evident that a hypnoid level cannot be reached, this method can do much to help a patient relax, both physically and mentally, and to alleviate an appreciable degree of anxiety and tension. If it is possible, I take this opportunity to hypnotize the patient, because with a deeper level of hypnosis valuable posthypnotic suggestions can be given. This "relaxing" technique is especially useful when working with patients who are poor operative risks, such as those with cardiac disease or allergies to commonly used anesthetic drugs or those scheduled to undergo cardiac surgery. This means of preoperative sedation and preparation establishes confidence, minimizes fear and anxiety, and makes the prospect of surgery more acceptable. The unavoidably great investment of time is well worthwhile because of the greater ease and safety with which the surgical procedure is carried out.

Hypnosis is a valuable method of inducing anesthesia or achieving basal anesthesia in children. A simple suggestive technique can induce anesthesia before tonsillectomy, for example, and enable one to make posthypnotic suggestions that render recovery from anesthesia more pleasant. The results in such cases are gratifying, because on recovery the children are more cheerful, more alert, more responsive, more comfortable, and more cooperative than those who undergo anesthesia induced by chemical agents alone.

Hypnosis is invaluable not only as a means of sedation before and after operation but as an auxiliary method of anesthesia or a means of achieving total anesthesia. Hypnoanalgesia is especially useful when employed in conjunction with other anesthetic procedures, because it reduces the amount of chemical agents used. I have used hypnoanalgesia successfully in association with epidural and spinal anesthesia when it was essential to obviate depression of the respiratory or the cardiac system with drugs. Hypnosis alone can be employed in such procedures as incision and drainage, short orthopedic operations, or extractions of teeth. It should be mentioned that hypnodontia is a well-recognized and highly useful field of dentistry.

Hypnosis may be used when changing painful dressings, as of burns, and while removing sutures when the patient is frightened. It has been used successfully to improve both the morale and appetite of badly burned men.[6] Hypnoanalgesia also eliminates depression of vital functions and protective reflexes and often prevents such accidents as palsies of ulnar nerves or excessive traction on brachial roots, because the hypnotized patient is aware of any painful pressures in an unanesthetized area. The use of hypnosis in obstetric delivery is well documented. However, the handling of the pregnant woman in this respect usually falls within the province of the obstetrician.[7]

Posthypnotic suggestion is perhaps the single most valuable phenomenon associated with hypnosis. Many suggestions effective in lessening the incidence and severity of nausea and vomiting may be carried out with remarkable accuracy. Such suggestions can relieve postoperative pain, reduce the amount of narcotics used, and help the patient to breathe deeply or to cough. Review of the literature has failed to reveal any reports of the use of hypnoanalgesia or hypnoanesthesia in thoracic surgery. The surgical operations involving the use of hypnosis that have been reported on in the modern literature are laparotomy,[8] bilateral mammaplasty,[9] appendectomy [10] and amputation.[11] Herewith is reported the first case in which hypnoanalgesia and hypnoanesthesia were employed in the resection of the lingula of the upper lobe of the left lung.

Report of a Case

A 25-year-old woman entered Cedars of Lebanon Hospital for bronchoscopic examination because of the presence of a lesion in the upper lobe of the left lung. On Jan. 6, 1955, with the patient anesthetized by hypnosis, a diagnostic bronchoscopic examination was performed. After the examination, it was decided that resection of the lingula was necessary and that the operation should be attempted under hypnosis because of the successful use of hypnoanalgesia during the bronchoscopic examination. The patient was hypnotized the night prior to surgery, and the suggestion was made that at a given signal in the morning she would be deeply relaxed and asleep and would respond only to the voices of the surgeons and the anesthetist. At 7:30 a. m. on Jan. 17, the patient was given 1½ grains (0.10 gm.) of pentobarbital (Nembutal) and 50 mg. of diphenhydramine (Benadryl) hydrochloride, by mouth. At 8:30, 100 mg. of meperidine (Demerol) hydrochloride and 1/150 of a grain (0.40 mg.) of scopolamine was administered. Hypnosis was begun at 10 a. m., and the patient was taken to the operating room at 10:30, when a deep hynotic level had been attained. An endotracheal tube was inserted while the larynx was directly visualized. Oxygen only was administered. Because the patient continued to swallow in the presence of the endotracheal tube, an intravenous injection of 50 mg. of thiamylal (Surital) sodium was given after an intravenous infusion of 5% dextrose in water had been begun. The skin was infiltrated with 25 cc. of a 1% solution of procaine hydrochloride, and an incision was made in the left side of the thoracic wall. Suggestion was continued throughout the procedure.

When the chest was opened, administration of 500 cc. of blood was begun. The patient responded to all commands except the one that she should hold her breath, which elicited resistance and resulted in more rapid breathing. Additional suggestion failed to produce the desired apnea. To prevent tearing of the lung during dissection, an intravenous drip of a 0.1% solution of succinylcholine was begun, and respiration was controlled. A total of 100 mg. was administered over a period of 45 minutes. Breathing returned to normal 30 seconds after withdrawal of the drug. Hypnotic suggestion was continued during the entire period of apnea as well as during closure of the wound. The operation ended at 1 p. m., when the tube was removed after the trachea was cleared. The resected lesion was a tuberculoma. Posthypnotic suggestion was given to the effect that postoperative discomfort would be minimal and that deep breathing and coughing would be easy. The patient was told to sleep for two hours and then awaken. The postoperative course was uneventful. The amount of narcotics used after surgery was minimal, and the patient was discharged on Jan. 25, in excellent condition.

Summary

Hypnosis has much to offer the anesthesiologist. It minimizes fear and apprehension and is valuable as an adjunct to the measures commonly employed in sedation before and after operation. It can be attempted when chemical anesthetics are contraindicated. Posthypnotic suggestion has proved to be of great value in the postoperative course, namely, in reducing or eliminating nausea, vomiting, and pain. Hypnosis is a successful auxiliary measure for inducing anesthesia and can effect anesthesia alone. Patients vary in their susceptibility to hypnosis, and a deep hypnotic level cannot be reached in every instance. Ideally, hypnosis should be used in combination with chemical agents to achieve anesthesia. The only disadvantage to hypnosis is that its effective application requires a considerable expenditure of time, a negative quality that is more than offset by its many advantages. Hypnoanalgesia was effectively employed during a resection of the lingula for tuberculoma of the upper lobe of the left lung in one patient.

NECROTIZING RENAL PAPILLITIS AND DIABETES MELLITUS

Fred W. Whitehouse, M.D.
and
Howard F. Root, M.D., Boston

• Necrosis of the renal papillae, ascribed to local ischemia and accompanied by general septicemia, was demonstrated in 10 instances in the course of 266 postmortem examinations of 416 diabetic patients who died during a five-year period; in addition the papillary necrosis was found in a kidney removed surgically from a diabetic patient who was relieved by the nephrectomy but who died two years later because of the functional inadequacy of the remaining kidney. To prevent this complication of diabetes, catheter drainage should be avoided whenever possible, and the importance of proper perineal hygiene in women should be emphasized. If genitourinary infections do occur, they should be treated vigorously with the correct antibiotic and obstructive uropathy should be eradicated; the diabetes should be well controlled. Necrotizing renal papillitis should be considered as a possibility whenever sepsis or progressive renal failure is observed in a diabetic patient.

Ischemic necrosis of the renal papillae and concomitant bacterial infection result in a clinicopathological entity variously known as necrotizing renal papillitis,[1] papillary necrosis,[2] medullary necrosis,[3] and necrotizing pyelonephritis.[4] Although the pathogenesis of the lesion is not completely understood, most authorities subscribe to the mechanism described above. Its close relationship to diabetes mellitus and obstructive uropathy has been emphasized.[5] Two recent reports[6] have adequately reviewed the literature. We would like to report our experience with necrotizing renal papillitis, based on cases studied at the New England Deaconess Hospital from January, 1950, to September, 1955. It should be pointed out that all patients reported on here were being treated at the Joslin Clinic and hence were drawn from a preponderantly diabetic population. All cases have been proved pathologically; no doubt exists as to the identity of any case.

Prior to 1950, necrotizing renal papillitis was indexed along with acute pyelonephritis. To review the experience prior to their separation would lead to inaccuracy of data; we will therefore limit this review to the subsequent years. There were 11 reports of necrotizing renal papillitis found in the files of the Joslin Clinic between January, 1950, and September, 1955. A study of these cases comprises the substance of this report. The table summarizes the clinical and pathological data on these patients.

Incidence and Concurrence with Diabetes

During the five-year period of this study, 14,252 diabetics were admitted to the New England Deaconess Hospital. During the same period, 416 diabetics died and 266 had postmortem examinations. Eleven cases of necrotizing renal papillitis were found: one in every 1,296 diabetics admitted and one in every 24 patients autopsied. Hence, necrotizing renal papillitis was found at 4.1% of autopsies on diabetic patients. The average age of our patients at the time of diagnosis was 60 years. The youngest patient was 26 years of age, the oldest 79. Females predominated 9:2 in our series. This is in keeping with past experience with diabetics.[7] All patients were white.

Diabetes mellitus was present in all patients. Ten patients were known to be diabetic at the time of admission, while one (case 8) was a newly discovered diabetic. The average duration of the diabetes was 14.8 years. The range was from newly discovered to 24 years. Three patients had had diabetes over 20 years and eight over 10 years. All but one were on insulin therapy. All patients were taking either protamine zinc insulin or isophane (NPH) insulin. The insulin requirement increased in six patients during their illness, rising from 50 to 100 units in one (case 5) and from 28 to 70 units in one (case 4). The average increase for the six patients was 24 units. In four patients the requirement did not change, and it fell from 40 to 20 units in one (case 9). Eight patients had evidence of diabetic retinopathy and three had diabetic neuropathy. Six patients had a previous diagnosis of diabetic nephropathy. An estimate of control of the diabetes in the patients in this series was difficult to assess. Arterial hypertension was present in four patients.

There are two clinical pictures associated with necrotizing renal papillitis.[1a] One, the acute fulminating type, is characterized by severe prostration, signs of overwhelming sepsis that may or may not be localized to the urinary tract, and rapidly progressive renal failure. Death occurs early and is usually ascribed to septicemia. The second or subacute type is characterized by a smoldering renal infection present for weeks or months, with acute exacerbations and terminal oliguria and uremia. An asymptomatic form has also been recognized. In our patients, the duration of the final illness (terminal hospital admission) ranged from three days (case 8) to six weeks (cases 1 and 10), with an average of three and one-half weeks.

Eight patients had fever at some time during the course of their illness. The number of days on which they had fever prior to hospitalization could not be ascertained with any degree of accuracy. Only 4 of the 11 patients had signs and symptoms suggesting urinary tract infection. In these patients, fever, chills, and flank pain were prominent. One patient had gross hematuria. The clinical picture in seven patients did not suggest renal infection. Six patients had previously diagnosed diabetic nephropathy. One case appeared after a sigmoid colectomy. An indwelling catheter was used in nine patients. Only three patients had oliguria. Ten of the 11 patients died. The patient in case 5 survived after removal of the left kidney.

From the Joslin Clinic and New England Deaconess Hospital. Dr. Whitehouse is now at the Henry Ford Hospital, Detroit.

Laboratory Findings

Ten patients had polymorphonuclear leukocytosis, with the number of white blood cells varying from 12,000 to 33,500. In two patients the nonprotein nitrogen level was between 40 and 50 mg. per 100 cc., in five it was between 50 and 100, and in four it rose above 100 mg. per 100 cc. One patient (case 6) had been in chronic uremia for over one year and entered the hospital with a nonprotein nitrogen level of 175 mg. per 100 cc. An elevated nonprotein nitrogen level receded toward normal in four patients. Examination of the urine was done frequently in all cases. Oliguria and anuria were not striking, in our experience. Only two patients had a daily urine output persistently below 500 cc. per 24 hours. A third patient (case 8) was oliguric on the day of death. The patient in case 11 presented with the chief complaint of "inability to urinate." This patient was totally anuric during one 24-hour period and was oliguric for eight days prior to death. The patient in case 9, with terminal diabetic nephropathy, was oliguric for a 10-day period during her final illness but in the last 48 hours of life voided a total of 1,400 cc. The remaining eight patients passed seemingly adequate amounts of urine, varying from 500 to 2,300 cc. per 24 hours. The table indicates the average 24-hour urinary output during the final five days of life.

There was significant albuminuria (over 20 mg. per 100 cc.) in 10 cases. Gross hematuria occurred in one patient, while microscopic hematuria was recorded in five cases. Pyuria was universal but highly variable, with the sediment showing only scattered pus cells on some occasions while at other times it was loaded with leukocytes. Cylindruria was recorded in seven cases, with mainly hyaline and fine and coarse granular casts present. These casts, of course, are commonly seen in the urine of patients with chronic renal disease. No documented papillary casts were identified. The urine was cultured in seven cases, while for four patients there was no record of culture. Escherichia coli and Proteus vulgaris were isolated in four cases each, growing out together in three. Micrococcus (Staphylococcus) pyogenes var. aureus was found in three cases. Two strains of streptococci and an Aerobacter were also isolated. In three of the seven patients with positive cultures, only one organism was found, while in four a mixed infection, with gram-negative organisms predominating, existed.

In the cases reviewed, x-ray studies were not used extensively as an aid in diagnosis. An intravenous pyelogram in the patient in case 5 showed a distorted calix at the lower pole of the left kidney. Roentgenograms of the abdomen in two patients were unrevealing. Retrograde pyelograms, suggested by Wall,[8] were not done.

Diagnosis and Treatment

An anatomic diagnosis was made in each patient, in 10 at postmortem examination and one (case 5) by nephrectomy. An intravenous pyelogram in this latter patient was interpreted as being suggestive of malignancy. Nephrectomy was carried out. Necrotizing renal papillitis and multiple cortical abscesses were found on pathological examination. The correct diagnosis was suggested ante mortem in only two cases. No case was proved ante mortem except in one patient (case 5). The usual pathological findings of ischemic infarction of the renal papillae associated with acute inflammation of the papillae and acute and chronic inflammation of the renal parenchyma was present in all cases. Eight patients showed unilateral papillitis, while three had bilateral involvement. Papillary necrosis was localized to two papillae each in three patients with unilateral involvement. Other significant postmortem findings are recorded in the table. In the two patients with concomitant diabetes and obstructive uropathy, acute pyelonephritis was bilateral but papillary necrosis was limited to the side with the obstruction.

All patients received some antibacterial agent (sulfonamide or antibiotic), usually more than one, during the course of their illness. In this series one can-

In October, 1955, Franke and Fuchs [1] and Bertram, Bendfeldt, and Otto [2] published the results of clinical trials of carbutamide in the treatment of diabetes mellitus. Reduction in blood sugar level and control of glycosuria were observed in 80% of diabetic patients receiving the drug. In April, 1956, the first American study of carbutamide therapy appeared in the literature in the form of a preliminary report by Ridolfo and Kirtley [3] confirming the German findings. Carbutamide, aside from its hypoglycemic properties, is a potent antibacterial agent. Substitution of a methyl group for the amino group of carbutamide (fig. 1) produced a compound without antibacterial potency but with unimpaired hypoglycemic activity. This compound, 1-butyl-3-*p*-tolylsulfonylurea, was designated U-2043 by the Germans and is known in the United States as tolbutamide, or by the trade name Orinase. The work of Stoetter in Germany and of Miller and Craig [4] and Kinsell, Brown, Friskey, and Michaels [5] in the United States suggests that tolbutamide has an order of effectiveness similar to that of carbutamide in the treatment of diabetes.

Fig. 1.—Chemical structure of two aryl sulfonylureas and sulfanilamide.

Pharmacology.—Carbutamide is rapidly absorbed from the gastrointestinal tract. In humans, after an orally given dose of 2 gm., blood levels of carbutamide rise almost vertically to peaks of about 14 mg. per 100 cc. within three to six hours, after which a slow decline begins. According to Achelis and Hardebeck,[6] acetylation of carbutamide does not appear to exceed 8 to 10%. Urinary concentrations of carbutamide, unlike those of other sulfonamides, are low and are predominantly in the acetylated form, suggesting a preferential excretion of acetylated carbutamide with reabsorption of free carbutamide. By virtue of this slow elimination, it behaves as a long-acting or "depot" sulfonamide in respect to its antibacterial effect, requiring, after an initial 4-gm. dose, only single daily 1-gm. doses for maintenance of effective blood levels. This long-acting property may be of significance in its antidiabetic action as well. Others, however, have reported 66% of urinary carbutamide to be in the free state.[3] Laboratory and clinical investigations have demonstrated antibacterial activity against many of the anticipated organisms, and the drug has been used successfully in the treatment of pneumonia, pharyngitis, and related illnesses.[6]

At blood carbutamide levels of 20 to 25 mg. per 100 cc., the blood sugar levels of normal fasting subjects will decline from a range of 100 to 110 mg. per 100 cc. to 70 to 80 mg. per 100 cc. for several hours, regardless of whether the material is given orally or intravenously.[6] Occasionally mild hypoglycemic symptoms are encountered, but severe reactions are unknown in humans.

While published pharmacological studies of tolbutamide are still incomplete, this drug appears to differ from carbutamide primarily in respect to bacteriostasis, which property it lacks. There seems to be little difference between the two in respect to hypoglycemic activity. Hypoglycemic responses have been induced by tolbutamide in mice, dogs, cats, rabbits, monkeys, and humans.[7] Premixing of the substance with a sodium bicarbonate solution sufficient to give a pH of 7.5 exaggerates the hypoglycemic response in rabbits.[7] Tolbutamide levels in the blood rise promptly after oral administration of the drug. According to Kinsell and co-workers,[5] the degree of its conjugation may influence its therapeutic effect in diabetics. In one patient with juvenile diabetes who responded to tolbutamide therapy with a decrease in insulin requirements, most of the drug was excreted in conjugated form; in another who did not respond, the greater portion of urinary tolbutamide was in the free form.[5] Acidification of urine is reported to precipitate a metabolically inactive excretion product,[8] in which the methyl group has been oxidized to a carboxyl radical.[9] At first these drugs were administered in initial doses of 3 gm.[7] followed by daily doses of 2 gm., and reduced to 1 gm. per day if clinical results permitted. However, in subsequent studies, dosages have varied from 1 to 12 gm. per day.

Toxicity.—Carbutamide and tolbutamide appear to be relatively nontoxic drugs. The L.D.$_{50}$ of orally given carbutamide in mice is 4 gm. per kilogram,[6] while that of tolbutamide is 2.5 to 3 gm. per kilogram.[7] Doses of 150 mg. per kilogram of tolbutamide given to dogs daily for two weeks produced no detectable pathological changes on gross and histological examination. The results of prolonged administration of these compounds to animals are under study,[7] but to date no pathological changes other than thyroid hyperplasia have been reported.[6] Liver, kidneys, and pancreas seem otherwise to be unaffected by tolbutamide, and weight loss, crystalluria, and peripheral blood or bone marrow changes have not as yet been recorded in these animals.[7] Severe hypoglycemia cannot be produced, regardless of dosage, except in rabbits when the drug is premixed with sodium bicarbonate.[7]

In humans, careful follow-up studies have revealed no serious untoward reactions thus far. Drug fever and drug eruptions due to carbutamide were encountered by German investigators in as high as 7.3% of patients,[2] but in all cases prompt remission followed termination of therapy. One case of jaundice has been reported in a German patient receiving carbutamide, but the prodromal symptoms of infectious hepatitis antedated the administration of the drug. Exhaustive studies of the urine, of hepatic and renal function, and of the blood in patients treated with carbutamide have been negative thus far.[3] Crystalluria has not been demonstrated even at blood levels as high as 200 mg. per 100 cc.[3] One patient with high blood carbutamide levels developed mental clouding, which cleared up on lowering the dosage. This same patient subsequently developed a skin rash and leukopenia, with a leukocyte count of 1,900 per cubic millimeter.[3] Very large doses of tolbutamide are reported to produce transient granulocytopenia due to a maturation arrest.[3] Reduction in radioactive iodine (I^{131}) uptake has been observed during the administration of these agents.[5] Except when they are given concomitantly with insulin, these drugs do not produce serious hypoglycemic shock in humans.

Clinical Results.—Franke and Fuchs[1] have reported that carbutamide reduced or corrected hyperglycemia and glycosuria in approximately 80% of their series of 50 diabetics. These favorable results were obtained in mild and moderately severe cases of adult diabetes, while the therapeutic failures occurred in the patients with severe juvenile diabetes, and in those in whom there was complicating infection or ketosis. Bertram and co-workers[2] have published the results of the treatment of 82 diabetics with carbutamide. In a group of 28 patients over the age of 49 with mild cases of diabetes, none of whom had been receiving insulin, all but 3 experienced significant reduction in fasting hyperglycemia and glycosuria. Of 38 diabetics treated with insulin in the same age group, in 28 the diabetes was satisfactorily controlled when carbutamide was abruptly substituted for insulin. In a third group of 10 patients, ranging in age from 15 to 40 years, with labile juvenile diabetes, carbutamide therapy did not significantly alter insulin requirements, although its inception was often attended by hypoglycemic reactions. The authors concluded that carbutamide is effective in diabetes of the "adult" type, characterized by mildness and stability of the disease, by a relative tolerance or hyposensitivity to insulin, by maturity at onset, and often by obesity. In contrast, failure to respond could be expected in the "juvenile" type of diabetes, characterized by severity and lability of the disease, by insulin sensitivity, by onset during youth, and by normal or subnormal weight. In addition, long duration of the disease in either type seemed to augur poor response. The results of these studies were confirmed in the United States by Ridolfo and Kirtley,[3] who reported a high percentage of therapeutic success in their series of 18 diabetics treated with carbutamide. Tolbutamide, though less extensively tested at first, has been reported to give comparable results.[10]

Mechanism of Action

The precise mechanism by which the aryl sulfonylurea drugs exert their hypoglycemic action remains to be elucidated. The original German workers[11] believed that these agents acted upon the alpha-cell system of the pancreas, causing a decrease in glucagon production. This antiglucagon theory is weakened by observations that alloxan diabetes, in which alpha-cell activity remains intact, does not respond to the sulfonylureas.[6]

A second hypothesis has been offered by Mirsky. His studies[12] of insulin degradation and those of Elgee and co-workers[13] have led him to conclude that there exists in tissues a specific enzyme, insulinase, responsible for insulin inactivation or destruction. According to Mirsky,[14] insulinase is counterbalanced by an insulinase inhibitor normally present in certain tissues. He has postulated that deficiency of insulinase inhibitor may be responsible for increased insulin destruction, resulting in the stable, insulin-tolerant type of diabetes so characteristic of the adult form of the disease.[14] Mirsky[15] has further demonstrated that insulinase activity and degradation of insulin are diminished by very high concentrations of tolbutamide, and he suggests, therefore, that the drug is a noncompetitive insulinase inhibitor and thereby slows the destruction of endogenous insulin.

Certain objections to the Mirsky hypothesis have been raised. If insulin-sparing were the mechanism of sulfonylurea action, one would expect metabolic alterations identical to those produced by insulin. Yet, whereas insulin induces glycogen accumulation in the muscles, the sulfonylureas do not.[15A] In further contrast to insulin-induced hypoglycemia, sulfonlyurea-induced hypoglycemia is accompanied by a more consistent increase in hepatic glycogen.[16] Another objection is the failure of sulfonylures to enhance, with any degree of consistency, the effect of exogenous insulin in patients with labile juvenile diabetes. Finally, Vaughan[17] has shown in vitro that tolbutamide in concentrations comparable to those producible in vivo does not cause insulinase inhibition. Her in vitro studies indicate that tolbutamide, which markedly diminishes epinephrine and glucagon-induced glucose release from rat liver slices, may do so by inhibiting one or more of several hepatic enzymes. Possible sites of action include glucose-6-phosphatase, phosphoglucomutase, or phosphokinase.[17]

Failure of the sulfonylureas to modify glucagon and epinephrine-induced hyperglycemia *in vivo*[8] has led to alternative speculation. Suppression of gluconeogenesis rather than of glycogenolysis may be the crucial action. Another theory, suggested by French workers, is that the sulfonylureas enhance beta-cell activity, thereby increasing insulin levels. Degranulation of beta cells is said to follow their administration, an observation that would support this concept.

Clinical Material

The 18 patients used in this study were diabetics admitted to the Dallas Veterans Administration Hospital. They were arbitrarily divided into four groups according to the type and severity of their disease. Group 1 includes three cases of the severe labile type usually seen in juvenile diabetics. In these cases insulin shock and ketosis were never far apart and discontinuation of insulin therapy was, therefore, impossible.

The patients ranged in age from 34 to 65. Onset of disease had been at the age of 24 in two cases and at 59 in the third. All were slim, though not malnourished.

Group 2 consisted of five individuals who had moderately severe stable diabetes, requiring insulin for adequate control. Withdrawal of insulin for 10 days or more in these patients was followed by an increase in glucose excretion to 25 gm. or more per day. They ranged from 51 to 65 years of age and, in all, diabetes had been discovered when the patient was over 40 years of age. Slight obesity was present in only one. This group included one patient (see table, patient 1, group 2) whose diabetes first became manifest while he was receiving high doses of steroids to suppress pemphigus.

Group 3 was composed of six patients with mild adult diabetes, with fasting blood sugar levels of over 150 mg. per 100 cc., who excreted less than 25 gm. of glucose per day during the control period. Their ages ranged from 38 to 61 years, and known duration of their diabetes was from three weeks to three years. One patient was slightly obese. In all cases glycosuria had been adequately controlled without insulin by carbohydrate restriction. Group 4 consisted of four patients with very mild adult diabetes whose fasting blood sugar levels never exceeded 150 mg. per 100 cc. and whose daily excretion of glucose did not exceed 1 gm. per day during the control period.

With the exception of the three patients in group 1 with labile diabetes, administration of insulin was discontinued in all patients for a control period of at least seven days prior to treatment with tolbutamide. In group 1 insulin dosages were reduced until the fasting blood sugar levels exceeded 250 mg. per 100 cc. and the daily glucose excretions exceeded 25 gm. Diets were prescribed according to the caloric requirements of the patient and were kept constant thereafter. Weights were checked daily.

Tolbutamide therapy was begun after a stable base line of seven days or more had been completed. The usual starting dose was 3 gm. given each morning on awakening. In all but the first three cases the drug was administered as 2% tolbutamide in 0.5% sodium bicarbonate solution. In these three cases, the patients were later re-treated with the tolbutamide solution. Whenever possible, on the first day of therapy food was withheld until six hourly blood sugar level determinations had been made so as to determine the degree of hypoglycemic response, if any, to a 3-gm. test dose of the drug. The 3-gm. dose would then be continued daily for five days or more, and, if response was unsatisfactory, the dose was raised in 3-gm. increments until satisfactory response was obtained. If at a daily dose of 12 gm. no favorable effect had been observed, administration of the drug was discontinued.

Evaluation of therapeutic results was based on whether the drug produced "worthwhile improvement in diabetic control" in patients receiving the calorically adequate diets. "Worthwhile improvement" was defined as suppression or substantial decrease in glycosuria or, if glycosuria had not been present before treatment, a reduction of 25% or more in the mean fasting blood sugar level. Minor decreases in the blood sugar level of doubtful clinical value were not counted as favorable responses. For example, a drop in the mean fasting blood sugar level from 145 to 130 mg. per 100 cc. in a patient with mild, previously aglycosuric diabetes was not considered a worthwhile result.

Effect of Tolbutamide Therapy on Mean Fasting Blood Sugar Levels and Mean Daily Glucose Excretion of Twelve Diabetics

†Patient 6 in group 2 was subsequently treated with 6 gm. of tolbutamide at bedtime, with reduction in mean fasting blood sugar level to 163 mg./100 cc.

Methods

Fasting blood sugar levels were determined each morning by the Folin-Wu method,[18] and determinations of 24-hour glucose excretion were made daily. Urinalyses, including examinations for crystalluria, were done twice weekly and complete blood cell counts, platelet counts, determinations of the blood urea nitrogen and blood cholesterol levels, and liver function tests were done periodically. Sulfobromophthalein (Bromsulfalein) excretion, I^{131} uptake, and protein-bound iodine level were determined in most cases before and at the end of tolbutamide therapy.

Results

Clinical Effectiveness.—Worthwhile improvement in control of diabetes, as defined above, was achieved in 7 of the 18 patients treated with tolbutamide (see table). This is an over-all response rate of 39%. In all patients weight remained constant throughout the period of observation.

Group 1: In the three patients in group 1 with severe labile diabetes, tolbutamide, administered after lowering insulin dosage to levels below the minimal requirements for adequate control, did not diminish glycosuria or fasting hyperglycemia in any case (see table). In one patient with extremely labile diabetes (fig. 2), profound insulin shock occurred on the fourth day of tolbutamide therapy, but daily fasting blood sugar levels and urinary glucose excretion increased progressively until, at dosage levels of 12 gm. daily, administration of the drug was discontinued and insulin dosage increased. Although severe hypoglycemic shock was not encountered in the other two patients, gradual deterioration in control was noted despite daily doses of 9 to 12 gm. In one (fig. 3) discontinuation of tolbutamide therapy without change in insulin dosage or diet was followed the next day by a startling drop in the fasting blood sugar level and glycosuria from 468 mg. per 100 cc. and 129 gm. to 53 mg. per 100 cc. and 0 gm., respectively, requiring prompt reduction in insulin dosage from 40 to 25 units. This apparent improvement was short-lived, however.

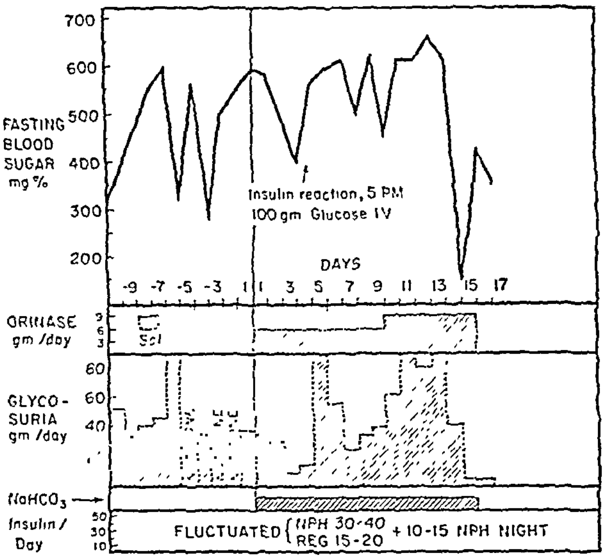

Fig. 2.—Therapy and course of patient 1, group 1 (see table), underweight, with labile diabetes of 11 years' duration, receiving inadequate doses of insulin (35 to 80 units). Addition of tolbutamide in doses of 6 and 9 gm. daily is associated with gradual deterioration of control and alarming episodes of hypoglycemic shock.

Group 2: In the patients in group 2 with moderately severe though stable adult diabetes, insulin withdrawal during the base-line period was followed by stabilization of the disease in a state of poor control, with fasting blood sugar levels of from 186 to 380 mg. per 100 cc. and daily glucose loss of from 25 to 80 gm. The administration of tolbutamide in doses as high as 12 gm. per day produced benefit in only one patient (see table, patient 6, group 2). In all other cases tolbutamide therapy was abandoned after two weeks and insulin therapy reinstituted in doses ranging from 15 to 45 units of isophane (NPH) insulin daily. Three of the four patients whose diabetes was clinically unresponsive had had favorable hypoglycemic responses to the test dose of tolbutamide when food was withheld on the first day of treatment. This responsiveness in the fasting state did not necessarily indicate clinical responsiveness on a calorically adequate diet.

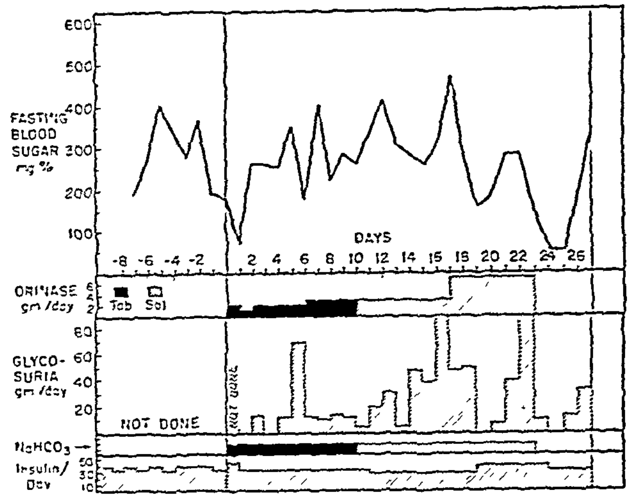

Fig. 3.—Therapy and course of patient 2, group 1 (see table), not obese, with labile diabetes of 10 years' duration, receiving inadequate doses of insulin. Progressive deterioration in control occurs while patient is receiving tolbutamide; its abrupt withdrawal was followed by apparent improvement of short duration.

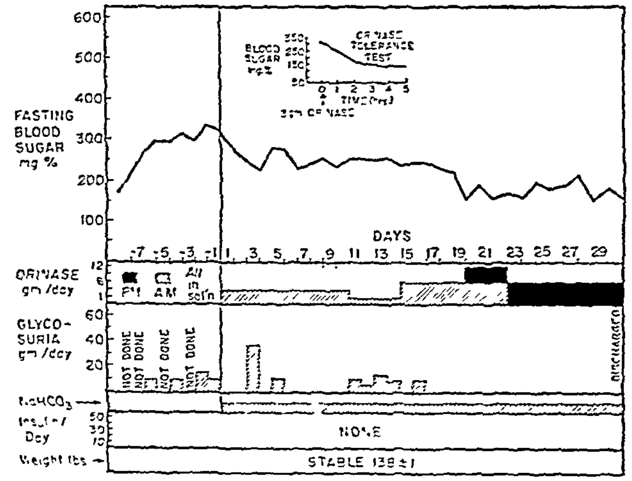

Fig. 4.—Typical chart of patient with tolbutamide-responsive diabetes (patient 3, group 3 [see table], not obese, with stable diabetes of 2½ years' duration and with old cerebrovascular accident), illustrating relationship of dosage and time of administration to therapeutic effect.

Group 3: Tolbutamide in doses of 3 gm. per day quickly diminished fasting hyperglycemia to levels well below 200 mg. per 100 cc. and completely eradicated glycosuria in the group 3 patients with mild adult diabetes, in all of whom the diabetes had been controlled on diet alone. It appeared that bedtime administration of the drug resulted in somewhat lower fasting blood sugar levels than did morning doses, but in most cases glycosuria ranging from 7.1 to 21 gm. per day before treatment disappeared, regardless of the time of administration. In one case (fig. 4) 6 gm. per day was necessary to suppress glycosuria completely. All patients in this group have been discharged, with instructions to continue taking 3 gm. of tolbutamide at bedtime, and their cases are being followed.

Group 4: The patients in group 4 with very mild adult diabetes were aglycosuric without any treatment, and their fasting blood sugar levels, though elevated, never exceeded 150 mg. per 100 cc. during the period of observation. All experienced significant hypoglycemic responses to test doses of tolbutamide, but reductions in these minimally elevated fasting blood sugar levels during tolbutamide therapy were not important enough to warrant prolonged administration of the drug. In one patient, amelioration of the oral glucose-tolerance curve was noted, though it remained distinctly diabetic in character. Since no treatment other than avoidance of sugar was warranted in these patients, it would seem unfair to consider them in the final analysis of the therapeutic efficacy of the drug.

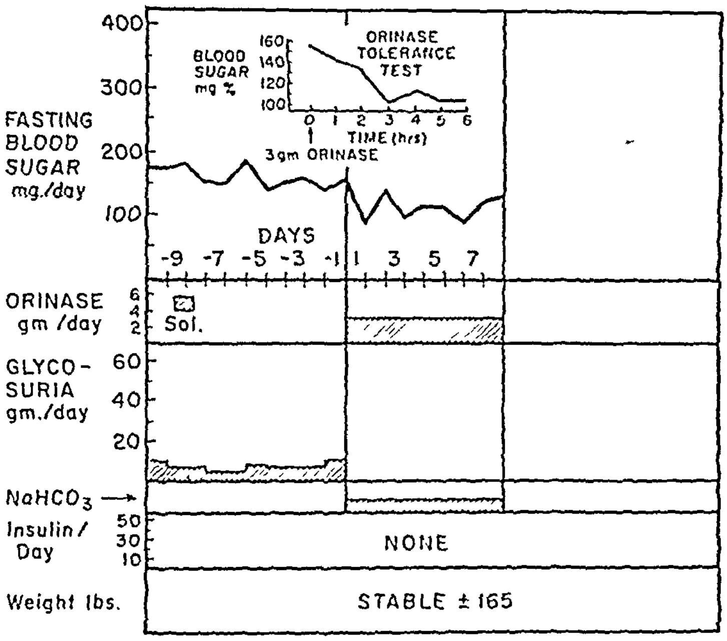

Fig. 5.—Typical chart of patient with mild, tolbutamide-responsive diabetes (patient 2, group 3 [see table], not obese, with stable diabetes of three weeks' duration).

Toxicity.—No untoward reactions were encountered in any of the 18 patients receiving tolbutamide. In none of the patients was weight loss, crystalluria, fever, or drug rash noted. No significant changes in complete blood cell counts, platelet counts, prothrombin times, hepatic function tests, urinalyses, determinations of cholesterol levels, sulfobromophthalein excretions, or I^{131} uptakes were observed during the period of hospitalization.

Clinical Evaluation

These results are essentially similar to those of previous authors. Any apparent differences result from variations in opinion as to the severity of diabetes and the indications for insulin administration. One source of error in evaluating the sulfonylureas stems from the fact that many patients with mild diabetes receive insulin unnecessarily, sometimes in rather large doses. Since in a surprising number of such patients the diabetes remains controlled after insulin withdrawal, abrupt substitution of a sulfonylurea drug for insulin without an intervening control period, as had been done in the earlier studies, can be misinterpreted as a favorable response and is not a valid method of study. A control period of insulin withdrawal should always precede the start of tolbutamide therapy in order to obtain a true picture of the therapeutic effect of the drug.

The questions of optimal dosage and time of administration require further study. It is our impression that 3 to 6 gm. of tolbutamide per day is needed in most patients to obtain maximal control. Bedtime doses, as might be expected, were superior to morning doses in lowering the fasting blood sugar level, though glycosuria was similarly suppressed by either. In one patient, premixing of tolbutamide with 0.5% sodium bicarbonate solution to form a 2% solution of tolbutamide seemed to be more effective than the tolbutamide tablets, and this method of administration was used in all subsequent cases. Sodium salts of tolbutamide may prove more effective by virtue of more complete intestinal absorption. A final observation of interest is that several patients with good hypoglycemic responses to test doses of tolbutamide given in a fasting state failed to have worthwhile clinical responses to identical doses given after they had resumed their diets.

Comment

The foregoing data seem to confirm previous clinical studies of the sulfonylureas and make possible certain tentative conclusions as to their current status in the treatment of diabetes mellitus. In the first place, it now seems abundantly clear that the sulfonylureas have no place in the therapy of labile diabetes. The danger of profound hypoglycemic reactions when insulin and sulfonylureas are given concomitantly to patients sensitive to insulin is considerable, particularly in the first week of therapy. Furthermore, there has been inadequate evidence that therapeutic benefit in this group ever occurs, and we have the impression that tolbutamide may at times aggravate the severity of the disease, as in the patient referred to in figure 3, whose condition seemed to deteriorate more rapidly when he was receiving large doses of the drug, but who improved dramatically when tolbutamide therapy was abruptly discontinued without change in insulin dosage or diet. It is possible that those sporadically reported patients with labile diabetes in whom sulfonylurea therapy seemed to permit a reduction in insulin dosage had been receiving overdoses of insulin prior to this. To eliminate this possibility, the insulin dosage should always be reduced to subminimal levels prior to the introduction of a second therapeutic agent.

The therapeutic activity of the sulfonylureas seems to be limited to stable diabetes, of which there were 15 cases in the present series. However, the three group 4 patients had diabetes that was too mild to have required treatment, and, although they "responded," the potential range of response was not wide enough to be considered worthwhile. Exclusion of these patients from consideration leaves 12 patients who had stable diabetes and who required treatment of some sort; in six cases insulin therapy had been necessary for adequate control of glycosuria, and in six diet alone had been effective. Of the six patients requiring insulin, in only one could the diabetes be controlled with tolbutamide, while in the group in which the diabetes was previously controlled by diet alone, all six responded to this drug In other words, of the seven patients with diabetes adequately controlled with tolbutamide (58% of the 12), only one had diabetes that was severe enough to have previously required insulin for control, while in all others the diabetes had been controlled with diet alone.

Speculation as to the ultimate place of the sulfonylureas in diabetotherapy is tempting though premature. Should long-term administration prove safe, most patients with stable diabetes would deserve a trial of sulfonylurea therapy. It is again emphasized that the drug should be given only after all previous treatment has been discontinued, so as to evaluate properly the therapeutic benefit. Thus, these drugs may make less stringent dietary restriction possible in many nonobese patients with stable diabetes, and to a lesser extent may replace insulin therapy in other patients with this type of diabetes who now require it for control. In addition it may provide an alternative to insulin therapy in certain obese diabetics who have been unsuccessful in attempts at weight reduction. One might, therefore, venture to predict a niche in the therapeutic spectrum between insulin treatment and dietary restriction A final observation of note was the failure of tolbutamide therapy to improve control of diabetes resulting from steroid administration.

Summary and Conclusions

In a study of the effect of tolbutamide (Orinase) therapy in 18 diabetics, daily oral administration of tolbutamide in doses of 3 to 6 gm. per day suppressed glycosuria and diminished fasting hyperglycemia in 7 of 12 patients with stable adult diabetes. All but one of the seven diabetics who responded to treatment had conditions that were mild enough to be adequately controlled by diet alone In only one case had insulin therapy been necessary for adequate control of the disease. Tolbutamide in large doses did not benefit patients with labile diabetes and caused hypoglycemic shock in one patient. One patient with diabetes provoked by steroid therapy did not benefit from tolbutamide.

Addendum

In continuing clinical trials of tolbutamide, two instances of skin reactions have been encountered. In one patient, diffuse erythema of the entire body appeared within four hours of the first dose but disappeared despite continued administration of tolbutamide. In the other patient, urticaria appeared but subsided without interruption of therapy.

4500 S. Lancaster Rd (2) (Dr. Unger).

The tolbutamide used in this study was supplied as Orinase by Dr C. J. O'Donovan of the Upjohn Company, Kalamazoo, Mich

Drs Donald W. Seldin and Holbrooke S Seltzer aided in the preparation of this report

Old Age.—The ability to learn "new things" declines with old age. There is more difficulty to comprehend visual or verbal stimuli which present new concepts and then to relate them to past experience. New situations, heretofore never experienced, calling for a new approach are troublesome to oldsters. In old age, tasks are more slowly performed, but accuracy and quality of performance may be better. The older person will do less well under time-stress. Rapid perception and motor coordination, known as "reaction time," decline with old age. Recent and immediate memory functions less well. Sensory acuity is often *diminished. However, reasoning ability,* finesse, "experience," and creativeness remain strong. Many years of living may bless one with a sensible sort of judgment and practical wisdom exercised very usefully in the affairs of everyday life. When abilities involving speed and time stress are removed, the difference of functioning between older and younger persons is less marked. It is noteworthy that some people "mellow" as they grow older. There occurs a passive but seemingly happy acquiescence, riding along with life and age as they come rather than fighting them The relief from responsibility, competitiveness, action and aggressiveness of youth appears welcome. A serene philosophy of life seems gradually to have accumulated. Somehow, continued everyday living has been of therapeutic and maturing value so that oldsters may be more comfortable within themselves than they were when they were younger.— J. A. Aita, M.D., The Ingredients of Old Age, *The Nebraska State Medical Journal,* May, 1956.

ACCIDENTAL CHEMICAL POISONINGS IN CHILDREN

Harold Jacobziner, M.D., New York

• *The possibility of preventing accidental poisoning (by chemicals other than illuminating gas) was studied by analyzing 454 cases that occurred in children under the age of 16 in New York City in 1954. Drugs were responsible for 47% of all poisonings, with aspirin ranking first and barbiturates second in this category. Among other chemicals, household bleaches were the chief offenders. Of the total of 454 cases, 84% occurred in children of the 0-3 year age group, and in this group lead was the responsible substance in 87% of the cases. Investigation of the circumstances generally revealed certain household practices as being at fault; in some environments the careless handling of materials, poor choice of storage places, and reckless changing of containers made eventual poisoning so likely that it could hardly be called accidental. Sanitary inspectors obtained valuable information, and visits by public health nurses proved effective in eliminating hazards. The physician can provide considerable health education during office visits, but he can also do much by observing existing health hazards during his home visits.*

Chemical poisonings (excluding those due to gas) are the third leading cause of death in children under 6 years of age in New York City. More children in this age group died from accidental poisonings in 1953 in New York City than from the following communicable diseases combined: measles, rubella (German measles), rheumatic fever and other streptococcic infections, poliomyelitis, diphtheria, whooping cough, and scarlet fever. During the same period 400 such deaths were reported in the same age group for the United States as a whole.[1] It is significant that the death rate from accidental poisoning in this group in the United States is fourfold that prevailing in England.[2]

The ever-increasing number of new chemical substances, drugs, and household preparations that appear on the market daily and soon find their way into homes influence the incidence of, and are perhaps responsible for, the substantial rise in accidental chemical poisonings. This study was designed to define and identify the various determining biological and environmental factors and to obtain more precise information on the epidemiology of fatal and nonfatal accidental poisonings.

Method of Study

Epidemiological investigations were made on 454 patients treated at hospitals. These investigations included hospital and home visits by sanitary inspectors of the environmental sanitation services. In selected cases, home visits were also made by public health nurses[3] and, in the case of lead intoxication, by epidemiologists of the bureau of preventable diseases. The analyses included identifying data, age, sex, race, type of poison, brand name (if any), location of poison, whether self-administered or given by another individual, amount ingested, symptoms, type of treatment (outpatient department or inpatient department), hospital diagnosis, laboratory determinations, and other pertinent remarks. This report is limited to 454 cases of chemical poisoning and 80 cases of lead intoxication, and only verified hospital diagnoses are included.

Results

The changes and variations with age are shown in table 1. The largest number of poisonings occurred in persons aged one; cases in this age group accounted for 34% of all poisonings. The next most dangerous age was 2 years. Aspirin was the chief offender in persons aged 2 and 3. Nearly 84% of all reported poisonings in children under 16 years of age occurred in children aged 1 to 4. The high incidence in this age group is undoubtedly related to the child's stage of growth and development. While given to exploration, the child has not yet learned through experience sufficient caution nor has he received the necessary education or protection from the adults in the family.

Types of Agents.—The various types of poisonings are listed in table 1. The number of individual substances involved is so numerous that a grouping by categories is necessary. Drugs were responsible for 47% of all poisonings in this study. Aspirin, particularly flavored or candied, was the chief offender, accounting for 75 occurrences, or 16.5% of all poisonings. Barbiturates were the next most frequent offenders in this category, followed by cosmetics. Of the household preparations, bleaches were the agents chiefly involved, accounting for 34 occurrences, followed by benzine and kerosene. Aspirin, barbiturates, bleaches, benzine, kerosene, lye, rodenticides, and insecticides

Read before the Ninth Clinical Meeting of the American Medical Association, Boston, Nov. 30, 1955.

were responsible for over 50% of all poisonings. Thus, if elementary precautionary measures had been taken with regard to these substances, over 50% of chemical poisonings in children would have been avoided.

Sex and Race.—Table 2 shows that 52% of the poisonings occurred in males and 48% in females. This is not statistically significant and could be ascribed merely to a chance occurrence. A significantly higher prevalence (25.5%) is observed (table 2) in nonwhite than in white children, a much higher incidence than would be expected from the composition of the general population, which is approximately 15% nonwhite. This observation is in agreement with findings of previous studies.[4]

Type of Treatment Agency.—Over 95% of the children were treated in hospitals and the majority (62.5%) in the emergency outpatient department facilities (table 3).

Fatalities.—Among the 454 cases investigated, exclusive of lead and gas poisonings, one death occurred. This death was due to salicylate intoxication in an 11-month-old girl who reportedly received about 100 grains (6.6 gm.) of aspirin in 48 hours. It was administered by the mother, who treated the baby for a condition that she diagnosed as a "cold and fever." No physician was in attendance, and the patient was dead on arrival at the hospital.

Location of Injurious Agent.—Forty per cent of all poisonings studied were due to injurious agents that were available in open places, such as floor, sink, table, dresser, open shelf, and chair (table 4). In an additional 74 occurrences (16%), the agents were located in closed places, such as dresser, cabinet, shelf, and drawer. Many of these places were unlocked and within the child's reach. Accidental poisonings occur in direct proportion to the degree of accessibility of the toxic substances, as has been suggested previously.[2b]

Seasonal Distribution.—Poisonings were more frequent (60%) in the first six months of the year (table 5). The reason for this is not quite clear; however, it is impossible to draw valid conclusions on the basis of one year's experience.

Lead Poisonings

A total of 80 verified cases of lead poisoning occurred in 1954. A confirmed diagnosis by the bureau of preventable diseases includes a history of ingestion of a lead-containing substance, pica, clinical findings, an analysis of a sample of the substance ingested for lead content, and analyses of blood lead levels or lead content in organs. It may also include x-ray determinations and examination for basophilic stippling. It is not implied that all criteria were confirmed in each case. In table 6 are presented pertinent data relating to age, sex, and race distribution.

The highest incidence of lead poisoning was found in persons aged 2, followed by those aged one and then aged 3. Persons in this age group accounted for 87.5% of the total. No difference in incidence by sex was observed in this series. There was, however, a striking variation by race. Thirty-five per cent of the cases occurred in nonwhite children, a significantly higher percentage than would be expected from the general population composition. An analysis of lead poisonings in children admitted for treatment in municipal hospitals during 1954 shows an even greater race difference, with 55% in the nonwhite group (table 7). The municipal hospitals, however, serve a large

segment of this population, which may explain in part the high nonwhite incidence in this group. It is interesting that there was a marked preponderance of females in this group. This is particularly difficult to explain, since the citywide figures did not reveal any sex distribution difference. It is possible that the female in this population group is more vulnerable to the effects of lead intoxication. The number of cases is, of course, too small for any valid conclusions. Thirteen deaths resulted from lead intoxication in children under age 16; no deaths were reported in children 6 years of age or older (table 8). Over 76% of he fatalities occurred during the summer months, me to September. The reason for this seasonal disibution is still obscure and deserves greater scrutiny. Metabolic disturbances and dehydration may be contributory factors.

Lead poisoning is not an uncommon disease in young children, and often it may be asymptomatic and undiscovered. Encephalitis may occur even before any mild symptoms characteristic of early lead poisoning have developed, such as weakness, irritability, headache, anorexia, pallor out of proportion to the anemia, and vomiting. It was also observed recently that, when other young children are examined in a household where a case of lead poisoning is diagnosed, these children, though entirely asymptomatic, may also show evidence of lead intoxication in laboratory blood and urine lead investigations. This is understandable, since these children are subject to the same environmental factors, such as substandard housing in which paint containing lead is used and where plaster flakes, wall plaster, and paint peelings from window sills are easily accessible.[5]

Multiplicity of Toxic Substances Involved

Ninety distinct types of substances, from aspirin to liniment, representing 164 different brands, were responsible for the 454 poisonings reported. For example, there were 7 brands of perfume, 8 brands of rodenticides, 12 brands of insecticides, and 10 different types of bleach preparations. (For convenience in analysis, these were placed in the categories represented in the tables.) This highlights the large number of products available in the American home, all of which if misused may be responsible for fatal and nonfatal mishaps.

Misplacing and Misuse of Agents

The removal of a substance from the original container and its transfer to a household utensil was a contributory factor to the occurrence of many serious poisonings; for example, iodine stored in an antacid bottle. Household bleach, one of the most common offenders, was found stored in a mayonnaise jar, drinking glass, soda bottle, or baby's bottle; gasoline and white gas were stored in coffee cans and cola drink bottles. In 14 instances kerosene was not in the original container but in a glass jar, drinking glass, coffee pot, cola drink bottle, and glass pitcher to catch drippings from the stove. Lye was left on a spoon after use, in a measuring cup, and in a tin box; paint was found in tin cans, coffee cans, and garbage cans; and turpentine was stored in glass jars, soda bottles, teacups, soup can, and glass containers. Gentian violet pills were ingested by three children in one family who thought they were candy. Insecticides were found spread on paper, on potatoes, and in cola bottles. Mouse seeds, which were involved in 15 occurrences and which contain 0.5% strychnine, were found in kitchen dishes, saucers, and other places. In only three instances were they found in the original containers. Rat poison was found in paper cups.

In addition, all these poisons were easily accessible to children, since they were stored, in the main, on the floor, in the sink, on the table, in open ledge cabinets, and in washtubs. One incident occurred when a home-made soap containing lye and fat was put in a basin in the sink to cool off and a 2-year-old boy obtained the basin and ingested some of its contents.

Home Visiting

Sanitary inspectors and public health nurses, in addition to obtaining valuable epidemiological information on the many whys and wherefores of poisoning causation during their home visits, also found a high degree of ignorance on the part of parents and other adults in the family concerning the potential hazards of drugs and household preparations. Parents were also woefully ignorant about the danger of children eating wall plaster, paint flakes, and paint from window sills. Visits to the home by public health nurses on accidents are invaluable. Nurses are readily accepted into homes, and families are willing to give them information and to obtain needed aid and guidance.

TABLE 7.—*Cases of Lead Poisoning in Children Admitted for Treatment in Municipal Hospitals, by Age, Race, and Sex*

	Nonwhite	21	5	5	5	6	...
Total		65	14	25	13	13	...

* Figures in parentheses indicate number of fatalities.

The public health nurse has been skillful in motivating families not only to institute needed safety measures but to follow through promptly on any other health problems. Referrals to appropriate treatment agencies for either prenatal care or health supervision and immunization of infants and young children were made in practically every case. Following are excerpts from a typical report by a nurse about an episode of a one-year-old child ingesting furniture polish.

> The child swallowed furniture polish. He and his sister had been left alone for a few minutes while his mother was in the basement. His crying summoned the mother, who telephoned the family physician. . . . The parents sleep in the living room on the couch. There is a large kitchen between the living room and the children's bedroom. It is the room in which the accident happened. The polish is kept in the cabinet near the floor. The children undid the small towel tied in a knot over the door handles of the cabinet, a makeshift expedient intended to serve as a lock.
>
> The apartment was inadequately wired. Sockets were overloaded. This was pointed out and the fire hazard stressed. A lamp cord in the living room was badly frayed. It was within easy reach of the children. Danger of severe shock, burns, and electrocution was pointed out to the mother. She was informed that the same danger existed when the electric cleaner, the iron, the toaster, or any electrical appliance was plugged into the socket, if the connecting cord was broken or frayed. The lamp was disconnected by the mother and put aside. It was emphasized, and the mother agreed, that the wooden gate at the head of the cellar stairs was at best a precautionary measure; likewise the fence surrounding the premises. The mother agreed that eternal vigilance and supervision of the children is the only safety measure that can be depended on.
>
> The mother was advised to follow her private physician's advice concerning overweight. She weighs 209 lb. She was advised to observe the diet prescribed. Nurse plans to visit again to issue literature on safety and obesity, to assist the mother to become more safety minded, and to help her in following her doctor's recommendations.

Nurses are thus not limiting their efforts on home visits to safety alone nor to the child population concerned but are actually translating this experience and their enthusiasm into action in all of their many other activities and are thus making a notable contribution to the prevention of all types of accidents in all age groups and to public health in general.

How Accidents Happened

Except in 32 incidents, children ingested the toxic substance because it was easily accessible and within their reach. Of the other 32 incidents, 9 were suicidal attempts in older children. The agents involved were mainly barbiturates, though iodine, roach powder, and aspirin were also incriminated. In three other instances older children, 13 to 15 years of age, took the toxic substances mistakenly for other medicaments, such as eye drops for nose drops, iodine because it was in an antacid bottle, and a rodenticide containing strychnine that was found on a shelf and mistakenly taken for tea. The remaining 21 cases were due to the administration of the toxic substance to infants varying in age from 11 days to 2½ years by adults or older siblings, either as overdosages or as mistaken medicaments.

Effect of Socioeconomic Factors

While no ethnic, religious, racial, or socioeconomic group is exempt, the risk was found to be considerably higher in the nonwhite group and in the lower socioeconomic levels. It is believed that the higher incidence in the nonwhite group is not due to any genetic or inherent constitutional factors but is merely a reflection of socioeconomic status. Ignorance, substandard housing, and overcrowding are definitely predisposing factors. A distinct correlation exists between substandard housing and lead poisoning, since most of the poisonings occurred in low socioeconomic areas where wall plaster, paint flakes, and window sill paint peelings containing lead were ingested by young children. It is possible, however, that the disparity may not be as great as is apparent, since many poisonings in the higher socioeconomic areas may not be reported.

Underreporting of Poisonings

Though reporting of poisonings due to drugs and of inhalation or ingestion of toxic agents is mandatory in New York City, the law has been observed chiefly by nonobservance both by hospitals and by practicing physicians. Only a small fraction of such cases were reported prior to the establishment of the Poison Control Center in March, 1955. The previous underreporting is evidenced in many ways: 1. While previously only several hundred episodes were reported annually, over 2,200 such incidents were reported to the Poison Control Center in an eight-month period. 2. During 1954, 14 municipal hospitals alone admitted on their wards 304 children under 16 years of age for the treatment of poisoning. In another six-month period, 128 children between 1 and 4 years of age with poisoning were admitted on wards of municipal hospitals.[6] 3. Twenty-six deaths from poisoning were reported in children under age 16 in New York City during 1954. It is conservatively estimated that for every fatal case there are about 150 nonfatal occurrences.[7] Thus, the actual number of accidental poisonings in New York City is perhaps over 4,000 annually.

Preventability

All accidental poisonings herein reported were carefully scrutinized, and, exclusive of the few suicidal attempts, it was definitely determined that they were all preventable; in no instance could it be established that the case was unavoidable.

Comment

"Accidental poisonings" are not accidental. It would have been an accident indeed if a poisoning had not taken place in most of the incidents studied. All the prerequisite ingredients for the occurrence of an accident were present; i. e., a toxic substance, an inexperienced host, and an unsafe environment. In many cases the total environment was so manipulated that an occurrence was unavoidable. Although I do not wish to minimize the importance of proper labeling of contents, it is doubtful whether this measure alone will help materially to reduce the large number of needless poisonings, as many persons do not read the label, many cannot read it, and many do not find the label content meaningful.

Though there is still a paucity of knowledge about nonfatal poisonings, a formidable body of information already exists about fatal poisonings, which, if appropriately applied, would aid in the reduction and control of chemical poisonings. The control of chemical poisonings is a collective responsibility and requires the skills and concerted action of many professions and disciplines. It is not merely a medical or paramedical problem alone, but one of engineering, industry, public health, sanitation, education, law enforcement, housing, social work, and basic investigative research. It is strongly believed that the basic epidemiological tools that have proved so potent in the control of communicable diseases will prove just as effective in the control of poisonings, for accidental poisonings also follow a distinct epidemiological pattern.[8] It is not enough to study the toxic agent, its pharmacological action, and its specific antidote, if any. A sound preventive program implies a thorough knowledge of all the facts about the agent, host, and environment—where, when, why, and to whom chemical poisonings happen.

Solving the Problem.—The prevention of chemical poisonings is a difficult, multifaceted, and complex problem; but it is capable of solution. The problem must be properly identified and defined and appropriate countermeasures applied to the most vulnerable population and to areas with the greatest need. A relentless war must be waged on all fronts in order to reduce the large number of needless poisonings.

What the Practicing Physician Can Do.—Though the modern physician no longer limits his practice to therapeutics but engages extensively in preventive medicine, there is still a wide lack of sufficient awareness and interest on the part of many physicians to incorporate home safety and accident prevention as an integral part of their daily practice. While the health and protection of children are primarily responsibilities of the family, the physician has a distinct obligation as health advisor and counselor to the family in helping it to obtain an ideal state of well-being and optimal health for its children. Working with people and disseminating knowledge and health promotion are not strange roles to the practicing physician. These activities have served him well in the control of many illnesses, and it is believed that they will be equally effective in the control of chemical poisonings.

Health Education: Health education is of incalculable aid in any health program, but it is essential in an accident control program. Reliable and precise information, without any overdramatization, on all the factors and forces responsible for the many needless chemical poisonings must be provided and told by the physician in a simple but effective manner. Parent, adult, and child education about the hazards of medicaments and household preparations will prove a potent force in preventing many poisonings. While it is not easy to alter genetic or biological factors, habits, and attitudes, environmental factors can be altered. Because of the family physician's intimate knowledge of the child's growth and development, the family's cultural and social background, the family's customs and traditions, the total home environment, and the parents' and child's habits and attitudes, the physician is in a most strategic position to become a dominant member of the poisoning-prevention team.

The physician must assume his obligation and become better informed by obtaining a wider knowledge about the health hazards of drugs and the many household preparations. This knowledge should not only be with regard to symptomatology and therapeutics involved; it should be used to continually educate parents and children on the potential hazards of these substances. Physicians can provide considerable health education and guidance during office visits for periodic health supervision and for immunization against communicable diseases. The physician also has a rare opportunity to practice health education and preventive medicine at its best during his home visits for the care of the sick. While in the home he can carefully observe any existing health hazards and influence parents on the need to acquire safe habits and attitudes and to institute and maintain safety precautions in and about the home in order to safeguard the lives and the well-being of their children.

Careful and Specific Directions: Careful and specific directions should be given to parents by the physician when medicaments are prescribed. Only small quantities to fill immediate need should be prescribed.

Parents should be strongly advised to keep medicaments and all household preparations in the original containers under lock and key and out of reach of children. Parents should also be advised by physicians at every opportunity against self-medication.

Other Measures: The physician can also aid immeasurably by prompt and complete reporting of all accidental poisonings in persons under his care to the local health department. The epidemiological data thus obtained will serve as important guides for sound preventive programs. As a member of the local medical society, a physician can be helpful in influencing the establishment of a poison control center in his community. As a leading citizen in the community, the physician can also aid in motivating community groups, both public and voluntary, to mobilize their efforts in solving the problem of chemical poisonings.

Summary and Conclusions

Four hundred fifty-four cases of accidental chemical poisoning (excluding those due to gas) occurred in children under 16 years of age in New York City in 1954. Of the total number, 84% occurred in persons in the age group 0-3 years. The high incidence in this age group is related to the child's exploratory nature coupled with inexperience and lack of caution. Drugs were responsible for 47% of all poisonings, with aspirin as the chief offender and barbiturates as the second leading cause in this category. Bleaches were the chief offenders of the household preparations.

No significant sex differences in incidence were observed, but a striking difference was noted in incidence by race, with cases in nonwhites greatly predominating. This possibly reflects socioeconomic conditions, such as substandard housing and overcrowding, rather than inherent constitutional differences.

Lead intoxication was observed most frequently in persons in the age group 1-3, cases in this group accounting for 87% of the total. Over 76% of the fatal lead poisonings occurred during the months June-September. Removal of substances from the original container and transfer to a household utensil was a contributory factor in many poisonings. A disproportionate number of accidents occurred in the poor socioeconomic areas. Lack of adult supervision and disregard of elementary precautions were frequently observed. Ignorance on the part of families about hazards of chemical preparations was a contributing and predisposing factor.

Prevention of poisoning requires a team approach. It is a medical, social, and community problem, and all skills and disciplines must play a part in its solution. A comprehensive and dynamic program is needed, with stress on the most vulnerable group, areas of greatest need, and the most common offending agents. Further investigative research is needed on all aspects of the problem. A comprehensive, effective program of education is imperative. The family physician is a key person in prevention of poisoning, and health education is the keystone.

CLINICAL NOTES

CLINICAL EVALUATION OF A NEW NEUTRAL DETERGENT BAR

Frederick Swanson, M.D., New York

The use of cleansing agents on the skin is designed to remove all exogenous agents deposited on its surface as well as some of the materials that have been produced by the skin itself (e. g., sebum, sweat, and scales). The conventional cleansing agents, namely, the toilet soaps, fulfill these requirements in an eminently satisfactory fashion on most normal skins. On skin that is abnormally dry, sensitive, or diseased, however, the common toilet soaps not infrequently cause irritation and produce a sensation of excessive dryness, burning, and also, at times, itching. These undesirable effects of soaps on sensitive and abnormal skins are in part, at least, attributable to their alkalizing action in aqueous solution. Since soaps are salts of the weakly ionized fatty acids and the strongly ionized alkalis, an alkaline solution always results on hydrolysis. This alkaline solution is generally well tolerated when soaps are used within reason on "normal" healthy skin, for the surface of the healthy skin, by means of surface acids, buffer systems, and other homeostatic mechanisms, is able to maintain or recover its required acid pH, which ranges from about 3.5 to 6.0. However, the normal acidifying mechanisms are almost always impaired when the skin is damaged, inflamed, diseased, or in other ways abnormally sensitive; and it is then that the damaging effects of the alkaline soap solutions are most likely to occur. Because of these undesirable characteristics of ordinary soaps, dermatologists for many years have recommended that patients sensitive to soap use detergents that have an acid or neutral pH. While these are not entirely free from harmful effects on the skin, they lack one of the principal undesirable properties of soaps, i. e., their alkalizing action. Among the drawbacks that have interfered with the more widespread acceptance of many of the nonalkaline detergents is the fact that their lathering properties

often are poor and that, with one or two exceptions, they have been available only in liquid form rather than in the much handier and more practical cake or bar form to which the users of toilet soaps are accustomed.

TABLE 1.—*Tolerance to Neutral Detergent Bar in Patients with Various Dermatoses*

	Total No. of Subjects	Tolerance: Good No.	Good %	Poor No.	Poor %
Group 1—Dermatoses that are often intolerant to toilet soaps

Group 3—Dermatoses that are usually tolerant to toilet soaps					
Acne vulgaris and acneform eruptions	39	38	97.5	1	2.5
Total	200	172	86	28	14

Recently a mild neutral detergent bar has been evaluated by us in a series of human subjects. This bar (Dove), which lathers very well, contains as its active ingredient an anionic detergent, an acyl isethionate, which is made by condensing fatty acids with sodium isethionate. It is combined with a fatty acid emollient and plasticizer along with perfume and other minor ingredients. Dove lathers are essentially neutral (pH 7), unlike soaps that give lathers with an alkaline reaction (pH 10). The 200 subjects in whom the neutral detergent bar was evaluated were dermatological patients, many of whom were deliberately selected because they were suffering from dermatoses that are notoriously intolerant to soaps. In addition to receiving whatever other treatment was indicated for their dermatosis, they were to use the neutral detergent bar as the sole cleansing agent. The evaluation of the skin's tolerance of the neutral detergent bar was based upon clinical observations regarding the occurrence of irritation, including erythema, dryness, scaling, fissuring, or worsening of the patient's dermatosis, as well as upon the subjective response of the patients, such as development of dryness, burning, itching, or "tightness" of skin. At least during the first month or two of the therapeutic trials, the patients were seen at intervals of one to two weeks. In those instances where there was doubtful tolerance of the neutral detergent bar, patients were told to continue its use until tolerance or intolerance had been established.

The test subjects were divided into three groups, on the basis of what was known regarding tolerance of their dermatoses to commonly used toilet soaps: Group 1 consisted of those who had dermatoses that often are intolerant to toilet soaps (such as atopic dermatitis, infantile eczema, contact dermatitis, nummular eczema, "housewives' eczema," eczematous fungous infections, dermatitis of the hands, excessive dryness of the skin, pruritus senilis, and winter itch eczema). Group 2 consisted of those who suffered from dermatoses that are sometimes intolerant to toilet soaps (such as seborrheic dermatitis, intertrigo, and irritated and relatively acute forms of psoriasis). Group 3 consisted of those who had dermatoses that are usually tolerant to, and in fact often benefited by, the use of toilet soaps (such as acne vulgaris, acneform eruptions, and seborrhea).

Results

The results in these three groups of patients are presented in table 1. As is well known, toilet soaps are generally less well tolerated by older people, because their skin naturally tends to be relatively dry. Moreover, it was of interest to assay the tolerance to the neutral detergent bar of infants and very young children. For purposes of comparing the skin tolerance to the neutral detergent bar in the various age groups, the 200 subjects under study were divided into three age groups, as shown in table 2. No evidence of allergic sensitization was observed in any of the 200 test subjects, nor in many hundreds of other subjects with and without skin diseases who have used the neutral detergent bar but who are not included in this report.

Comment

The results presented in table 1 show that 86% of all the dermatological patients tolerated the neutral detergent bar, while 14% had poor tolerance. A distinct difference was noted in tolerance between the three groups: patients in group 1 (atopic dermatitis, eczema) showed poor tolerance in 17% of cases, and patients in group 2 (seborrheic dermatitis, irritated psoriasis) showed poor tolerance in 15% of cases, while only 2.5% of the patients in group 3 (acne, seborrhea) did not continue use of the neutral detergent bar. These figures must, of course, be considered in the light of what probably would have been the reaction of these subjects' skin to regular use of toilet soaps. All the test subjects had dermatological difficulties, and four-fifths of them were suffering from dermatoses that are either always or often intolerant to or aggravated by soaps. The fact that most subjects were able to use the neutral detergent bar indicates a distinctly better tolerance as compared with common toilet soaps. This was especially striking in the 135 patients who had dermatoses in which many, if not most, dermatologists [1] would routinely interdict the use of soaps. The breakdown of the results for the different age groups (table 2) shows that patients from the age group 50-79, who often have soap-sensitive, dry skins, tolerated the neutral detergent bar just as well as patients in the age group 5-49. Moreover, the neutral detergent bar was well tolerated in a high proportion of infants and young children, almost all of whom had infantile eczema or other eczematous eruptions.

TABLE 2.—*Tolerance in Various Age Groups*

Age Group, Yr.	Total No. of Subjects	Good No.	Good %	Poor No.	Poor %
1-4	31	27	87	4	13
5-49	106	90	85	16	15
50-79	63	55	87	8	13
Total	200	172	86	28	14

Summary

A neutral detergent bar (Dove), which gives a lather with a pH of 7, was evaluated in a selected group of 200 dermatological patients. Of these, 135 had dermatoses often intolerant to commonly used toilet soaps and 26 had dermatoses sometimes intolerant to these soaps. Eighty-three to 85% of the patients with presumably generally poor tolerance for toilet soaps showed no signs of ill-effects from the regular use of the neutral detergent bar. No differences were found in tolerance to the neutral detergent bar between the age groups of 1 to 4, 5 to 49, and 50 to 79. The results suggest a much better skin tolerance among these dermatological patients to the neutral detergent bar than to commonly used toilet soaps. It is inferred that this difference, to a large extent, may be due to the neutral pH (7) of the neutral detergent bar lathers, as compared with the quite alkaline (pH 10) lathers of most commonly used toilet soaps.

330 Second Ave. (3).

The soap used in this study is manufactured by Lever Brothers Company, New York.

TUBERCULOMA OF SPINAL CORD

James B. Dibble, M.D.
and
Joseph Cascino, M.D., Chicago

The incidence of formation of tuberculous granulomas of the spinal cord is rare enough that we thought it worthwhile to report in detail a case we have recently observed. The first tuberculoma of the spinal cord was described in 1830 by Serre[1] in France. During the following 105 years only 87 such cases have been described in the world literature.[2] In reviewing the literature since 1935, we have been able to find only 84 more cases in the English-speaking literature.

The pathogenesis of tuberculoma of the spinal cord is now thought to be[3]: 1. A tubercle forms in the spinal cord or in the membranes, being blood-borne in the vast majority of instances. 2. This tubercle provokes a reactive phenomenon that causes proliferation of powerful connective tissue elements that form the granuloma. 3. Drainage persists into and by the subarachnoid space. 4. An inflammatory reaction occurs in the piarachnoid, and a secondary meningitis is set up. This explains the clinical picture frequently seen, i. e., the manifestation of tuberculous meningitis before cord-pressure symptoms occur. Of Anderson's four cases of spinal cord tuberculoma, in three there was an antecedent history of meningitis.[4] In our case, tuberculous meningitis had occurred four months previously, at which time symptoms of cord damage were present but not recognized as such.

Report of a Case

A 32-year-old female entered Cook County Hospital, Chicago, on Dec. 20, 1954, with meningitis as diagnosed in the examining room. Two weeks before admission she had left work because of headache and "feeling hot." She became gradually weaker, had periods of urinary incontinence, and had periods of disorientation. She was seen by two physicians, both of whom made a diagnosis of "flu." Two days before admission she was seen at a local hospital and sent home with the diagnosis of "flu." On admission to a female medical ward, the physical findings (positive and significant negative) were as follows: temperature 101 F (38.3 C), pulse rate 80 per minute, blood pressure 120/80 mm. Hg, respirations 18 per minute; lethargy and disorientation; marked nuchal rigidity; Brudzinski sign positive; "waxy flexibility" of the whole body; apical systolic murmur grade 2; appendectomy scar; and deep tendon reflexes bilaterally equal. No other abnormal neurological findings and no pathological reflexes were noted. Spinal tap revealed opening pressure of 280 mm. H_2O; clear colorless fluid; Pandy reaction 2+; 700 white blood cells per cubic millimeter, with 86% lymphocytes; smear (immediate) and culture (later) negative for tubercle bacilli; and test for Queckenstedt sign not done.

The presumptive diagnosis of tuberculous meningitis was made, and the following day the patient was started on antituberculosis medication: isoniazid, 100 mg. three times daily; aminosalicylic acid, 4 gm. three times daily; streptomycin, 2 gm. every morning; and penicillin, 600,000 units every morning. During the next week the patient gradually improved. The temperature became normal in nine days and remained normal. Her lethargy and disorientation disappeared. The tuberculin test 1:1,000 was negative, but positive to 1:100. A repeat spinal tap on the 19th hospital day showed opening pressure of 145 mm. H_2O; xanthochromia; glucose 163 mg. per 100 cc.; Pandy reaction 2+; 532 white blood cells per cubic millimeter, with 86% lymphocytes; protein over 1,000 mg. per 100 cc.; negative smear (immediate) and culture (later) for acid-fast bacilli; and test for Queckenstedt sign not done.

An interesting, though at that time unexplained, complaint was occasional inability to void, necessitating catheterizations. The significance of this finding was discussed at length a number of times, but no satisfactory cause could be found. On Jan. 21, the 23rd hospital day, the patient was transferred to the Oak Forest Tuberculosis Hospital for continuance of long-term antituberculosis therapy. She received intensive therapy uninterruptedly for the next four months.

Four months later, on May 12, 1955, the patient reentered Cook County Hospital with the complaint of progressive weakness of the left leg and progressive anesthesia of the right leg of 10 days' duration. At Oak Forest she had continued to need occasional catheterizations for inability to void. Cystoscopy had been done and showed only mild cystitis. A spinal tap had been normal and was negative for acid-fast bacilli on smear and culture early in her course at Oak Forest. A spinal tap done the day before readmission to Cook County Hospital showed a complete block to the Queckenstedt maneuver, and the removed fluid clotted in one minute. X-rays of the spine showed no bony pathology. Physical examination on readmission showed temperature of 98.6 F (37 C), pulse rate 86 per minute, and blood pressure 106/72 mm. Hg.; point tenderness on the 5th, 6th, and 8th thoracic vertebrae; hemianesthesia to the 8th thoracic vertebra on the right side; hemianesthesia to the 10th thoracic vertebra on the left side; hemiparesis to the 8th thoracic vertebra on the left side; cranial nerves intact; and bilaterally positive Babinski signs. Spinal tap revealed an opening pressure of 50 mm. H_2O, complete block on the Queckenstedt maneuver, and smear negative for tubercle bacilli. The hemoglobin and urine examinations were normal.

The patient was seen by the neurosurgery service 36 hours after admission, and an emergency laminectomy was performed 12 hours later. At surgery, laminectomy was performed from the 4th to 7th thoracic vertebrae. There was pulsation of the cord only to the 4th thoracic vertebra. The meninges were thickened greatly over the entire length of cord exposed. At the level of the 5th and 6th thoracic vertebrae was a grayish-pink homogenous tumor mass, measuring approximately 3.5 cm. in

---

Surgical Resident, Cook County Hospital (Dr. Dibble) and Attending Neurosurgeon, Cook County Hospital (Dr. Cascino).

length and 1 cm. in thickness. It completely surrounded the cord at the level of the 6th thoracic vertebra, the greater part of it being posterior to the cord itself. Incision in this mass produced 2 cc. of thick liquid yellow pus. The posterior two-thirds of the tumor was resected for decompression and biopsy. A drain was left down to the cord. This was removed on the fourth postoperative day. Biopsy showed "areas of necrosis surrounded by granulomatous areas suggestive of tuberculosis. Langhan's type of giant cells are seen." For the first 10 days postoperatively there was total paraplegia, undoubtedly due to the edema of surgery. Then gradual improvement began, and during the next month all evidence of sensory loss was gone, except for small patchy areas of hypesthesia, and motor power had returned to near normal in the right leg and was present, although weakly, in the left leg. Bowel and bladder control, lost in the immediate postoperative period, returned. Antituberculosis therapy was continued.

On June 28, 1955, six months after her original illness and six weeks after laminectomy, the patient was returned to Oak Forest for continuation of therapy on a convalescent basis.

Comment

This case falls into the group of tuberculomas of the cord classified as extramedullary, in contradistinction to the intramedullary tumors, since it could be "peeled" from the cord at surgery and seemed to be limited to the membranes surrounding the cord. It is extremely difficult to differentiate preoperatively between the two types,[5] and, therefore, exploratory operation should be done as soon as possible in all cases where localizing signs and symptoms are present. Our criterion for surgery in this case was, of course, the exstreme rapidity of progression of symptoms. This picture of rapidly changing or progressing symptoms is also stressed by Weinberg.[5] We felt that we had everything to gain and nothing to lose by immediate surgery.

Conclusions

A plea for early laminectomy is made in those patients with (1) a history of tuberculous meningitis and (2) localizing neurological findings. We are seeing at Cook County Hospital more and more recurrences of tuberculosis infection where initial intensive antituberculosis therapy is not maintained for at least one year. We do not know how much longer is indicated.

1825 W. Harrison St. (12) (Dr. Dibble).

Lupus Erythematosus.—Seven patients with chronic resistant lupus erythematosus showed considerable to complete involution of their lesions within two to four months of therapy with Plaquenil. It appears to be at least as efficient as quinacrine or chloroquine. Preliminary experience confirms pharmacologic evidence that Plaquenil is the least toxic of these three synthetic antimalarials. It does not stain.—T. Cornbleet, M.D., Discoid Lupus Erythematosus Treated with Plaquenil, *A. M. A. Archives of Dermatology and Syphilology*, June, 1956.

SYMMETRICAL CEREBRAL CALCIFICATION ASSOCIATED WITH PARATHYROID ADENOMA

Warren P. Knuth, M.D.
and
Paul Kisner, M.D., Lincoln, Neb.

The presence of symmetrical cerebral calcification, particularly in the region of the basal ganglions, has been reported in connection with a wide variety of different disease entities. This subject was investigated and the literature extensively reviewed by Eaton, Camp, and Love in 1936. They added an additional six cases to the literature, the condition in all of which was diagnosed ante mortem by means of skull roentgenograms. They noted that parathyroid insufficiency was frequently seen to accompany this condition. They emphasized that roentgenograms should be taken of the skulls of all patients with hypoparathyroid tetany. Subsequent reports have confirmed the original impression of Eaton and his co-workers,[1] and, in 1947, Camp[2] reported a series of 12 cases in which the patients had roentgenographically demonstrable symmetric cerebral calcification and parathyroid insufficiency. However, inasmuch as there has been no instance of hyperparathyroidism or parathyroid adenoma in any of these reported cases, the case which is presented herein is thought to be of unusual interest.

Report of a Case

The patient, a 58-year-old male, was first seen at this hospital on Jan. 8, 1952, when he was admitted in a comatose state with the diagnosis of cerebral hemorrhage. It was difficult to obtain an adequate history, but it was learned that the patient had been discharged from the Army in 1918 because of "fits." Thereafter he obtained work as a laborer until 1935, at which time he became unemployed and his only activity was helping with housework. During 1941, his family first noticed his having episodes characterized by stiffening of the arms, a drawn face, and failure to respond to questioning. Since 1943 he had walked with his arms and hands flexed and had developed a stooped posture. During this period there was also a pronounced mental deterioration that continued progressively up to the time of his death. In 1950, the patient was found unconscious on the floor. He remained semicomatose for several days but finally recovered. In the next two years, he was frequently brought home by police after having a "spell" while out walking, but after each attack he recovered without specific therapy. It was learned that the patient's father, who died in 1943, had had a "nervous disposition," and two siblings who died in early childhood were said to have been mentally deficient.

On the morning of admission to the hospital, the patient was found in bed unconscious and, after being seen by the family physician, was brought in by ambulance. On examination, the patient was comatose and breathing stertorously with Cheyne-Stokes respirations. The rectal temperature was 101.4 F (38.5 C), respirations were 18, pulse rate was 140, and blood pressure was 110/60 mm. Hg. The skin was hot and dry, and there was slight resistance to flexion of the neck. The neck veins were not distended, and the thyroid gland was found normal. There was a rotatory slow movement of the eyes, which came to rest turning to the right and upward. The right pupil was larger than the left and both reacted to light. The extraocular movement showed no evidence of conjugate deviation. Examination of the optic fundi was negative. The chest and heart were negative except for a tachycardia with a rate of 140 per minute, and the abdomen, genitalia, and rectum revealed no abnormalities. All four extremities were hypertonic; the feet were held in extension, with the left leg somewhat more hypertonic than the right. Deep tendon reflexes were hyperactive but equal, and the abdominal and cremasteric reflexes were sluggish. The Babinski sign was present on the left and the Hoffman sign absent. There was no clonus.

From the Veterans Administration Hospital.

Laboratory Data.—The red blood cell count was 4,400,000 per cubic millimeter; hemoglobin level, 14.6 gm. per 100 cc.; and white blood cell count, 9,600 per cubic millimeter, with polymorphonuclear cells 89% and lymphocytes 11%. Serologic tests were negative. In urine studies, the specific gravity was found to be 1.008 and the urine negative for albumin and for sugar; there were 0-3 white blood cells and 0-2 red blood cells per high-power field. The nonprotein nitrogen value was 39.5 mg. per 100 cc., the fasting blood sugar level 196 mg. per 100 cc., the carbon dioxide-combining power 72 vol. %, and the chloride determination 112 mEq. per liter. The spinal fluid was clear and colorless: value for glucose was 137 mg. per 100 cc. and for protein 44 mg. per 100 cc.; the globulin was normal, the colloidal gold determination 0000000000, and lymphocytes were one per cubic millimeter. The chest x-ray film was normal. The skull films showed extensive symmetrical calcification bilaterally in the region of the caudate nuclei and flake-like calcifications bilaterally in the brain substance of the frontal lobe (fig. 1).

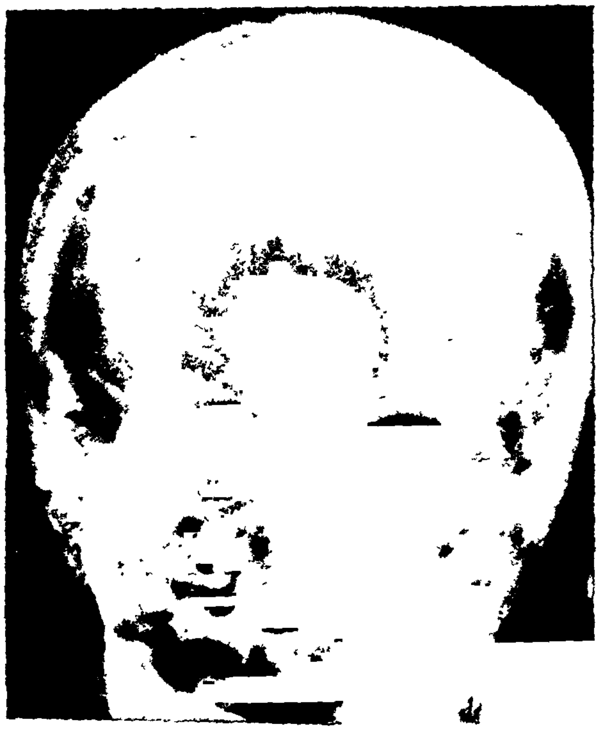

Fig. 1.—Anteroposterior roentgenogram showing symmetrical cerebral calcification involving principally the basal ganglions.

Hospital Course.—On the second day in the hospital the patient was alert, the sensorium was clear, and the response to questioning was relevant but fragmentary. The patient seemed to be in good contact but at times exhibited pathological crying. He moved all extremities in a slow and awkward manner. He was noted to hold his hands rigid and flexed. Two weeks after admission, a pneumoencephalogram was performed that showed the previously described cerebral calcifications to be outside the internal capsule, involving the putamen and globus pallidus. In addition, there was dilatation of the lateral ventricles to two to three times normal size and excessive subarachnoid air indicating bilateral symmetrical cerebral atrophy. In further laboratory studies, the total serum cholesterol was 290 mg. per 100 cc., calcium 12.4 mg. per 100 cc. (normal range, 9.0-11.5 mg. per 100 cc.), and phosphorus 3.0 mg. per 100 cc. (normal range 3.0-4.7 mg. per 100 cc.). Blood sugar at this time was 126 mg. per 100 cc.

Treatment consisted of general supportive measures as well as anticonvulsant and antibiotic therapy. A slight improvement was noted. During this period several episodes occurred in which the patient was semicomatose and the temperature was elevated to 102-104 F (38.8-40 C). During these episodes, the eyes were deviated to the right. There were intermittent grunting respirations and there was a coarse tremor of the left hand. He was finally discharged to a nursing home.

Second Admission.—The patient was again admitted two years later after a similar episode of unconsciousness. After he regained consciousness, the patient was given a general physical examination. Findings were similar to those at the time of the previous admission, but the patient exhibited far-advanced emotional and intellectual deterioration. During his hospital stay, he had several grand mal seizures that were reasonably well controlled with use of diphenylhydantoin and barbiturates. Treatment became mainly a problem of nursing care, and he was treated symptomatically. Nine months after his second admission, the patient suddenly had a severe convulsive seizure, during which he became dyspneic and cyanosed and developed shock and peripheral circulatory collapse. He died 30 minutes later.

Autopsy.—Findings at autopsy determined death to be caused by a myocardial infarction at the apex of the heart secondary to occlusion of the anterior descending branch of the left coronary artery. The brain weighed 1,260 gm., and there was considerable cortical atrophy. There was cerebral arteriosclerosis and the lateral ventricles were found on cut section to be enlarged twice the normal size. There was diffuse calcification of the basal ganglionic region. The histological picture of the calcifications was identical to that described by Eaton and coworkers[3] and consisted of a deposit of hematoxylin-staining material in the nervous tissue and in and about the blood vessels. These deposits varied in size and, in some areas, were found in the media, adventitia, and perivascular spaces of arterioles and capillaries (fig. 2). Some areas showed coalescence of the globules into calcified sheets.

When the thyroid glands were removed, the right gland was slightly larger than the left and of softer consistency. Cut section through the structure demonstrated a cystic cavity in its center, and microscopic examination revealed it to be parathyroid tissue. There was a small compressed rim of thyroid tissue at the periphery of the section. The adenoma consisted principally of slightly enlarged, uniformly shaped chief cells (fig. 3). The cell outline was not too distinct and the cytoplasm appeared pale pink and slightly granular but not deeply eosinophile such as is seen in the oxyphil cell. Examination of the remainder of the viscera revealed several small areas of abnormal calcium deposits of microscopic size within the renal parenchyma but none elsewhere.

Comment

The case report presented herein very closely resembles the sequence of events reported as occurring in hypoparathyroidism, associated with bilateral cerebral calcification. The onset of the disease is early in life and is characterized by intermittent episodes of convulsive seizures and gradually progressive intellectual and emotional deterioration. However, when the patient was first seen at this hospital, blood chemistry determinations indicated a relative hyperparathyroidism rather than parathyroid insufficiency. In addi-

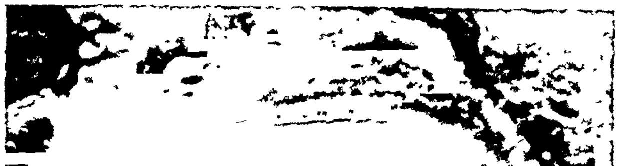

Fig. 2.—Photomicrograph showing deposits of calcium within a small artery.

tion, at autopsy a large cystic adenoma was found in a parathyroid gland and microscopic calcific deposits were present in the kidneys.

As in the case of most neoplasms, the cause of parathyroid adenomas is unknown. Inasmuch as adenomas occasionally appear in several glands in the same patient, Albright and Reifenstein[4] have suggested that the observation by Erdheim in 1907 may be worthy of consideration. This is that "germinative centers" exist in hyperplastic glands and these centers may in some way lose their ability to be controlled by normal stimuli and develop into adenomas. One can only speculate as to the relationship of the bilateral cerebral calcification, the parathyroid adenoma, and the hyperparathyroidism as noted by blood chemistry determinations. It might be assumed that a state of hypoparathyroidism may have existed for many years and the parathyroid adenoma developed as a process of compensatory hyperplasia until eventually a state of hyperparathyroidism was attained. Because of the absence of a satisfactory history and inadequate blood chemistry determinations over a prolonged period of time, it is not felt that any conclusions can be drawn from this case. The case is presented primarily from the standpoint of its unique clinical and postmortem findings.

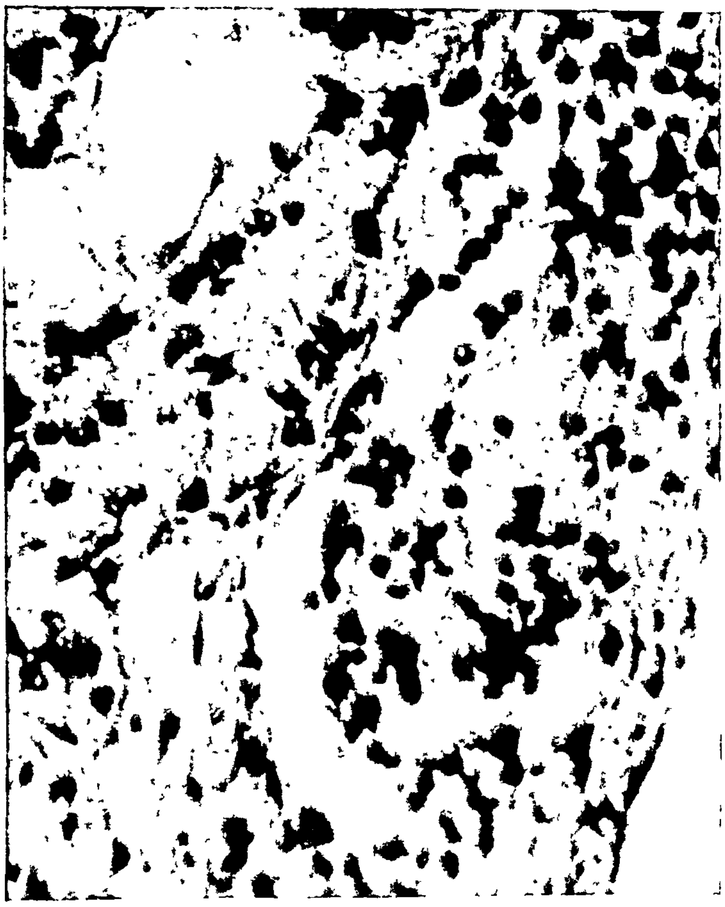

Fig. 3.—Photomicrograph showing the structure of the parathyroid adenoma discovered at autopsy.

SPECIAL ARTICLE

LONGEVITY AND CAUSES OF DEATH FROM IRRADIATION IN PHYSICIANS

Shields Warren, M.D., Boston

Data bearing on effects of prolonged low-level exposure of man to ionizing radiation are few. With the use of atomic energy becoming more general and the increasing probability of large portions of the population becoming potentially exposed to radiation, the value of such data materially increases. I add herewith some observations. Radiologists and certain other groups of medical specialists, such as dermatologists, urologists, and gastroenterologists, have experienced prolonged occupational exposure near or sometimes slightly above the present permissible levels of radiation. While some of the pioneers in radiology risked themselves freely, paying with radiation-induced leukemia or carcinoma for their absorption in their new and untried tool to aid humanity, most of those utilizing ionizing radiation in their medical work have received only small doses.

Dose Levels of Irradiation

The present permissible level of total body radiation accepted by the International Committee on Radiation Protection for x-rays or gamma rays of less than 3 mev energy is 0.3 r per week (in the blood-forming organs, gonads, or eyes), which means, for a 30-year working life at the maximum permissible dose level, a total occupational exposure of 468 r. The U. S. National Committee on Radiation Protection had recommended in handbook 15 of the National Bureau of Standards, issued in 1931, a permissible level four times as great, or 200 mr per day. This was reduced in 1936 to 100 mr per day in handbook 20, and again in 1949 to 50 mr per day in handbook 41. However, only recently have measurements of radiation been made in most radiology departments in this country, and even now few radiologists wear film badges or ionization chambers. The probability is that from 1930 to 1941, when the danger of ionizing radiation was not as completely appreciated as it is today, some physicians had exceeded this level and a number may have received a total dose of over 1,000 r. In the early years of work with radiation, total doses well above this were re-

ceived. Those physicians working an appreciable portion of their time with sources of ionizing radiation receive even now during their professional activities significant amounts of radiation. However, efforts are being made to minimize the doses received.[1]

There is evidence that doses of radiation are less effective in producing injury to somatic cells when protracted over a long time than when received in a brief period. It is common clinical experience that a given dose of local therapeutic radiation is less harmful to normal tissues when protracted than when administered in a single period. This is largely due to the reparative power of the exposed cells. Estimates of the acute lethal dose of total body irradiation for 50% of a human population are about 400 to 450 r. Yet many radiologists have received over this in divided doses.

The average person in the United States living at or near sea level receives somewhat under 150 mr per year,[2] or, by the time he has reached 60 years of age, he has received a total of 9 r from the total background radiation, much of it from radioactive elements in rock or soil, some from cosmic radiation. If he spends most of his life as a sailor, he will have received about one-third this amount of radiation.

Previous Studies

The longevity and causes of death of those physicians occupationally exposed to sources of ionizing radiation, even though adequately protected by past and current standards, may give information when contrasted with data on physicians as a whole and the general population. Already some such studies have been carried out. March[3] found that radiologists dying in the 15-year period from 1929 to 1943 had 10 times as many deaths from leukemia as did other physicians and again in the period from 1944 to 1948 found somewhat comparable data,[4] 4.8% deaths from leukemia in radiologists as compared with 0.7% in nonradiologists.

Henshaw and Hawkins[5] found 1.7 times as much leukemia in physicians as in white males in the United States in the period 1933 to 1943. Ulrich,[6] in a study similar to March's, found eight times as many deaths from leukemia among radiologists as among physicians practicing other specialties. Dublin and Speigelman[7] studied the mortality of medical specialists in the period 1938 to 1942. Among 175,146 physicians living in that period, 37,010 (21.1%) claimed to be full-time specialists. During the five-year period studied there were 12,419 deaths of physicians in the age group 35-74, and 2,029 (16.3%) of these deaths were of medical specialists. Since only 1.1% of the specialists who died were women, the sex ratio was not significant. The mortality ratio for specialists from all causes was 78%, taking the death rates of all physicians or 100%. They reported radiologists to have a mortality ratio of 0.90, dermatologists 0.98, and pathologists 0.60. They noted that radiologists show a high rate of mortality from cancer and leukemia, and deaths from leukemia among 95 recorded deaths of radiologists were higher than those in any other specialty.

Recent figures of the doses received by nonradiology personnel in diagnostic procedures such as angiography and cardiac catheterization indicated that doses up to 50 mr may reach the hands.[8] That radiologists and other specialists exposed to ionizing radiation receive possible genetic damage is suggested by the higher rate of congenital malformations reported in their children, 5.99% as against 4.84% in children of nonradiology specialists.[9] However, both rates appear unduly high and suggest some bias in the data. To remind one of the levels of radiation involved in diagnostic radiology, Kirsch[10] found that in typical roentgenologic examination the output as measured on the patient's skin in the center of the x-ray beam averaged 13.7 r for a gastrointestinal series, 4.9 r for a barium enema, and 6.4 r for a gallbladder series. However, the physician receives only a small portion of this output, chiefly in the form of scattered radiation during fluoroscopic examinations. The average daily exposure of some radiologists in 1936 and earlier was 12 mr per day.[11]

In the United Kingdom, where safety in radiology has been much more highly developed for some time than is the case in the United States, the doses received by radiologists are low. Osborn[12] reports the average weekly dose received by 5 trained therapeutic radiologists was 42 mr per week and for 13 trained diagnostic radiologists was 106 mr, the highest individual average dose being 230 mr; the highest dosage averaged for a week was 700 mr. In New Zealand, Jamieson[13] found two-thirds of the staff received less than 50 mr per week and only 2 of 24 received between 500 mr and 1 r per week. It has been estimated that the average amount of time spent by radiologists in fluoroscopy in the United States is 50 minutes per week.[14] This length of time combined with average exposure levels would indicate 40 mr per week received from fluoroscopy. If, however, the examiner is not protected by his lead apron, as when standing sideways to the beam, he may receive 200 mr per hour.[15] With care, exposures can be kept below one-tenth of the permissible level.[16]

In a recent unpublished survey of specialists in the Boston area using ionizing radiation, Spalding found the average weekly exposure of the upper arms and chests of 65 radiographers not doing fluoroscopy was 40 mr, while 72 doing some fluoroscopic work received 180 mr. Eleven dentists doing radiographic work received a weekly average exposure of 200 mr. Twelve dermatologists averaged 250 mr weekly and 4 urologists 470 mr weekly. Radioisotope workers receive lower doses than x-ray personnel, only one exceeding 300 mr in any week as against nine in radiology departments.[17]

There are some ways in which the effects of ionizing radiation resemble the aging process. Scattered cells become more variable in size, shape, and chromatin content than the normal; certain functions, such as formation of melanin pigment, tend to decrease; collagen tends to increase and hyalinize; elastic tissue tends to degenerate. Glucksmann[18] stresses the increased differentiation of cells after irradiation.

Experimentation with animals has demonstrated clearly, as in the work of Boche,[19] Blair,[20] and Hursh,[21] that total body radiation tends to shorten the life of an irradiated animal, and, indeed, within the limits of experimentation (from 25 r up to several times the lethal dose), a linear plot of the reduction in longevity with dose could be obtained. Blair[20] differentiates between the shortening of life of animals due to a single dose of radiation and discontinuous chronic radiation. On a single-dose basis he finds about a 20% shortening of life per 500 r, using rodents as the test animals. His chronic irradiation data indicate a shortening of life at the rate of 11% per 1,000 r. In the sequelae of single exposures, the acute radiation syndrome plays an important part. In chronic discontinuous radiation, the acute radiation syndrome does not appear, and hence such serious hazards as overwhelming infections and multiple internal hemorrhages are not factors in shortening of life.

Current Study

Statistical Sources.—In the current study the causes of death of physicians and their age at death are taken as given in the obituary columns of The Journal from Jan. 1, 1930, and continuing for 25 years through 1954. Any one year may include a few deaths occurring in earlier years, but there is no duplication. In the period from Jan. 1, 1930, through Dec. 31, 1954, 82,441 deaths were recorded. The specialty of the physician, if any, was usually stated. The specific cause of death was given in 65,545. In general, causes of death in physicians may be expected to be determined with somewhat greater accuracy than in the general public.

The age at death was stated for 79,027. As age at death is much more easily determined than cause of death and as the American Medical Association has much biographical data on physicians, we believe that our data for longevity are relatively accurate. Furthermore, since some evidence is accumulating to indicate that radiation may shorten life by other than the established radiation-induced diseases, age at death becomes perhaps more significant than cause.

The time of the study included World War II, as a result of which an abnormally large number of younger physicians were killed, and this might tend to reduce the average life span of physicians during this period. However, this should not affect the comparison of mortality and morbidity of those specialists exposed to ionizing radiation with those of specialists and nonspecialists assumed not to have been in significant contact with sources of ionizing radiation. The time is well after that during which unwittingly reckless exposure occurred, and so most of the early martyrs in radiology, who would unduly weight the data, are excluded. However, about 1930 the less cautious radiologists may well have received doses ranging up to 5 r per week, as unshielded glass x-ray tubes producing diffuse beams were in common use.

We have not checked the deaths of specialists against the membership lists of special medical societies, and hence some of the specialists may have been overlooked and included with nonspecialists. Undoubtedly some general practitioners and some nonradiology specialists devoted a portion of their time to radiological work and hence received amounts of ionizing radiation near those received by some of the radiologists. They cannot be identified by the techniques used in this study. However, those thus exposed to ionizing radiation would be included with the unexposed group and hence lessen the difference between the two groups, where there be any, rather than accentuate it.

Life Span.—The natural life span is under genetic control, but in large and heterogeneous populations, such as those dealt with here, genetic factors cannot be evaluated and do not have a significantly different effect. The life span of the several types of component cells of the human body varies materially, from the life of about three days of the lymphocyte and four days of the intestinal mucosal epithelial cell to the total life span of the individual as in the case of heart and striated muscle cells and neurons. The older cells aggregated in an organism age usually with evidence of accumulation of useless metabolic products, such as pigments, and show some cytoplasmic atrophy. While human cells in tissue culture appear to grow and be reproduced asexually indefinitely in a suitable environment, without the culture as a whole showing the appearance of age, the same types of cells grouped into an organism will show evidence of aging with the passage of time. In general, life of an organism ends when sufficient unfavorable stimuli accumulate. These may be such stimuli as external violence; bacterial, protozoal, or viral invasion; accumulation of metabolic products; or ionizing radiation. One may therefore conclude that a population showing a consistently shorter life span than the general is influenced by some unfavorable factors.

As man's environment has been made more favorable, the average age at time of death has increased to 65.6 years for males over 25 years of age in the United States in 1950. However, throughout recorded history, rare men have lived well beyond the average span, and the extreme life span has not lengthened.

Compilations of numbers of physicians in the United States vary between the American Medical Directory and the "Statistical Abstract of the United States." The 1950 edition of the American Medical Association Directory gives about 3,000 less than the statistical abstract. However, since the statistical abstract gives more recent figures, its lists from 1930 to 1953 will be used as giving the base line for total numbers of physicians. In comparing mortality of the medical population with that of the population of the U. S., we have used that group of general population 25 years of age or older, since physicians are practically all over 25 years of age. There were in this adult population group 74,775,836 in 1940; 88,116,411 in 1950, and 92,118,585 in 1953. In 1940 the death rates for this population were 16.1 per 1,000 for all causes as against 14.9 for physicians. The rates of 14.6 per 1,000 in 1950 and 14.6 in 1953 for the adult population contrast with a five-year (1950-1954) average rate for physicians of 14.5 per 1,000. Thus physicians have a mortality rate about the same as that of the general adult population.

The effect of the average age of various groups on morbidity and longevity of their numbers must be considered. Specialists might be expected to be older than nonspecialists, due to the longer training period, but the rapid influx of young men into the medical specialties since World War II has more than compensated for this. Pathologists were selected as a group comparable to radiologists, since they have the same length of training period and the same type of somewhat sedentary, largely institutional work. The two specialties also offer somewhat similar opportunities to physicians with physical handicaps. In 1954 there were 2,309 pathologists, with an average age of 48 years and a median age of 45 years, as compared with 4,038 radiologists, who had an average age of 47 years and a median age of 44 years. Thus the average age of these two groups is practically the same. They differ essentially only in exposure to radiation and in the much greater exposure of pathologists to infection. Pathologists have an average age at death of 62.4 years; the median is 63.3 years.

The average age at death for physicians not known to have contact with radiation is 65.7 years; that for radiologists is 60.5 years; and that for the specialists having some degree of exposure to ionizing radiation (gastroenterologists, tuberculosis specialists, and urologists, but excluding dermatologists) is 63.7 years. Dermatologists, who have been reputed to be somewhat more lax in protecting themselves against sources of ionizing radiation than other specialists, have an average age at death of 62.3 years. The average age at death for United States males over 25 years of age was 65.6 years in 1950.

Induced Diseases.—There are certain disease processes that have been induced by ionizing radiation in experimental animals and by accidental exposure in man and hence may be considered occupational hazards for radiologists and others in contact with sources of radiation. These diseases are cancer of the skin, leukemia, anemia, agranulocytosis, and osteogenic sarcoma. All have been encountered in the radiation-exposed group in the present study. In addition, induction of cancer of other sites may be considered a slight hazard, as radiation is known to be a factor in the production of certain cancers of the lung and possibly other types of malignant tumors. Time of induction of a tumor in man after exposure to ionizing radiation is variable. It may be fairly short (among the atomic bomb survivors in Hiroshima and Nagasaki, Japan, leukemia became more prevalent than among the control population in four years) or long (skin cancer or other neoplasms such as sarcoma have not appeared until 20 or more years after initial exposure).

Leukemia in 1950 killed 3.9 per 100,000 of the total population over 20 years of age. There were 120 deaths from leukemia among physicians during the period 1950-1954, or an average annual rate for the five-year period of 11.2 per 100,000. The death rate from leukemia for all physicians was thus about three times that for the adult population. As would be expected, leukemia shows a definitely higher percentage in the radiologists. In the period 1930-1954, 0.63% of the deaths from specified causes of physicians assumed not to have had exposure to radiation were due to leukemia, as against 2.33% for all specialists in contact with radiation and 3.65% for radiologists. During that same time period, the mean age of the nonradiologists dying from leukemia was 60 years, whereas the radiologists died from the disease at a mean age of 55.8 years.

The five-year average mortality rate from lung cancer for 1950-1954 was 18.3 per 100,000 for the adult population as contrasted with 18.7 for physicians. Too few cases (three only) were reported in radiologists to obtain meaningful figures. Cancer of all other sites had a death rate of 178.4 per 100,000 for the adult population in 1950 as compared with 128.5 for physicians.

Other Diseases.—Not only do radiologists and specialists exposed to some degree of radiation show a shorter mean life span than that of physicians assumed not to be exposed to radiation, but they die younger from practically every cause of death (see table).

Age at Death of Radiologists and Nonradiologists, 1930-1954

Cause	Physicians Not Exposed to Radiation	Radiologists
Neoplasms		
Leukemia	59.4	55.9
Carcinoma of skin	69.0	66.5
Carcinoma of lung	62.8	61.3
Carcinoma other sites	66.7	59.5
Degenerative Diseases		
Coronary disease	66.9	58.6
Myocarditis	72.5	53.0
Heart disease, nonspecific	67.1	62.8
Hypertension	70.7	66.1
Cerebral hemorrhage	69.1	60.0
Nephritis, type unspecified	65.1	64.5
Infectious Diseases		
Septicemia	58.4	46.0
Bronchopneumonia	69.7	63.5
Tuberculosis	56.3	51.3
Peptic Ulcer	63.0	35.5
All Other Stated Causes	66.4	61.9
Causes Not Stated	67.6	61.6

Thus, the nonradiologist dies from cancer, excluding leukemia, cancer of the skin, and cancer of the lung, at a mean age of 66.7 years, whereas the radiologists die of such cancers at a mean age of 59.5 years.

Radiologists die younger than do nonradiologists from every major cause of death with the exception of anemia. Here, the number of cases in radiologists may be too small to be significant. Nonradiologists died at an average age of 61.4 and radiologists at an average age of 63.8.[10] The discrepancy of 28 years in the case of death from peptic ulcer is particularly noteworthy, but the cases among radiologists are so few (three) that they are probably not significant. Thus, it is clear that not only are radiologists subject to certain occupational diseases but, furthermore, radiologists die from almost any cause of death at an earlier age than do nonradiologists. This strongly suggests that radiologists are subject to some common factor that lowers their resistance to disease and hastens the aging process. That this factor is ionizing radiation is strongly suggested by the fact that the practitioners

Experimentation with animals has demonstrated clearly, as in the work of Boche,[19] Blair,[20] and Hursh,[21] that total body radiation tends to shorten the life of an irradiated animal, and, indeed, within the limits of experimentation (from 25 r up to several times the lethal dose), a linear plot of the reduction in longevity with dose could be obtained. Blair[20] differentiates between the shortening of life of animals due to a single dose of radiation and discontinuous chronic radiation. On a single-dose basis he finds about a 20% shortening of life per 500 r, using rodents as the test animals. His chronic irradiation data indicate a shortening of life at the rate of 11% per 1,000 r. In the sequelae of single exposures, the acute radiation syndrome plays an important part. In chronic discontinuous radiation, the acute radiation syndrome does not pear, and hence such serious hazards as overwhelming infections and multiple internal hemorrhages are not factors in shortening of life.

Current Study

Statistical Sources.—In the current study the causes of death of physicians and their age at death are taken as given in the obituary columns of The Journal from Jan. 1, 1930, and continuing for 25 years through 1954. Any one year may include a few deaths occurring in earlier years, but there is no duplication. In the period from Jan. 1, 1930, through Dec. 31, 1954, 82,441 deaths were recorded. The specialty of the physician, if any, was usually stated. The specific cause of death was given in 65,545. In general, causes of death in physicians may be expected to be determined with somewhat greater accuracy than in the general public.

The age at death was stated for 79,027. As age at death is much more easily determined than cause of death and as the American Medical Association has much biographical data on physicians, we believe that our data for longevity are relatively accurate. Furthernore, since some evidence is accumulating to indicate iat radiation may shorten life by other than the established radiation-induced diseases, age at death becomes perhaps more significant than cause.

The time of the study included World War II, as a result of which an abnormally large number of younger physicians were killed, and this might tend to reduce the average life span of physicians during this period. However, this should not affect the comparison of mortality and morbidity of those specialists exposed to ionizing radiation with those of specialists and nonspecialists assumed not to have been in significant contact with sources of ionizing radiation. The time is well after that during which unwittingly reckless exposure occurred, and so most of the early martyrs in radiology, who would unduly weight the data, are excluded. However, about 1930 the less cautious radiologists may well have received doses ranging up to 5 r per week, as unshielded glass x-ray tubes producing diffuse beams were in common use.

We have not checked the deaths of specialists against the membership lists of special medical societies, and hence some of the specialists may have been overlooked and included with nonspecialists. Undoubtedly some general practitioners and some nonradiology specialists devoted a portion of their time to radiological work and hence received amounts of ionizing radiation near those received by some of the radiologists. They cannot be identified by the techniques used in this study. However, those thus exposed to ionizing radiation would be included with the unexposed group and hence lessen the difference between the two groups, where there be any, rather than accentuate it.

Life Span.—The natural life span is under genetic control, but in large and heterogeneous populations, such as those dealt with here, genetic factors cannot be evaluated and do not have a significantly different effect. The life span of the several types of component cells of the human body varies materially, from the life of about three days of the lymphocyte and four days of the intestinal mucosal epithelial cell to the total life span of the individual as in the case of heart and striated muscle cells and neurons. The older cells aggregated in an organism age usually with evidence of accumulation of useless metabolic products, such as pigments, and show some cytoplasmic atrophy. While human cells in tissue culture appear to grow and be reproduced asexually indefinitely in a suitable environment, without the culture as a whole showing the appearance of age, the same types of cells grouped into an organism will show evidence of aging with the passage of time. In general, life of an organism ends when sufficient unfavorable stimuli accumulate. These may be such stimuli as external violence; bacterial, protozoal, or viral invasion; accumulation of metabolic products; or ionizing radiation. One may therefore conclude that a population showing a consistently shorter life span than the general is influenced by some unfavorable factors.

As man's environment has been made more favorable, the average age at time of death has increased to 65.6 years for males over 25 years of age in the United States in 1950. However, throughout recorded history, rare men have lived well beyond the average span, and the extreme life span has not lengthened.

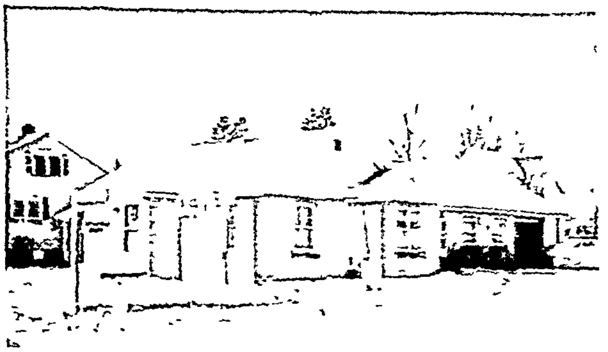
Compilations of numbers of physicians in the United States vary between the American Medical Directory and the "Statistical Abstract of the United States." The 1950 edition of the American Medical Association Directory gives about 3,000 less than the statistical abstract. However, since the statistical abstract gives more recent figures, its lists from 1930 to 1953 will be used as giving the base line for total numbers of physicians. In comparing mortality of the medical population with that of the population of the U. S., we have used that group of general population 25 years of age or older, since physicians are practically all over 25 years of age. There were in this adult population group 74,775,836 in 1940; 88,116,411 in 1950, and 92,118,585 in 1953. In 1940 the death rates for this population were 16.1 per 1,000 for all causes as against 14.9 for physicians. The rates of 14.6 per 1,000 in 1950 and 14.6 in 1953 for the adult population contrast with a five-year (1950-1954) average rate for physicians of 14.5 per 1,000. Thus physicians have a mortality rate about the same as that of the general adult population.

supply houses I have been able to finance all the equipment for the clinic. I hope to bring another physician to Owen within a year to help on the case load." (Dr. Braswell had three patients the day he unpacked, including an obstetric patient who had waited for the new doctor to arrive.)

This story of community leadership and planning is not a story of a handout; Dr. Braswell and Owen, Wis., see eye to eye on that point. He pays no rental the first 6 months, but will pay 24 months' rent during the remaining 18 months. Money collected after repayment to shareholders will go into other civic projects—a swimming pool or another professional building. Businessman Bulgrin told the people of Owen: "Forty years ago some of you may have started farming with a team and plow. It isn't that way anymore. It takes a lot of money and equipment for a young doctor to get started. They need help." It was Bulgrin who had gone to Chicago for help from the American Medical Association's Physicians Placement Service. This office, under the Council on Medical Service, operates as a clearing house for local medical societies across the nation. A large pin-studded wall map in the A. M. A. office indicates doctors and communities seeking each other.

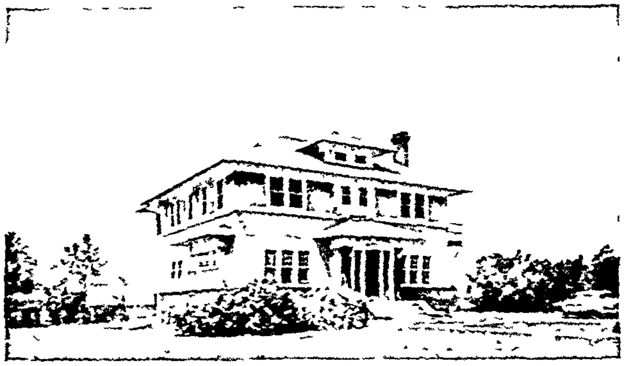
A Pin, a Blizzard, and a Buffalo

One day Miss Dorris Webb, staff assistant, stuck a colored pin into the map at Ennis, Mont. Until a doctor later came there by jeep, to stay, the closest physician was 80 miles away. A blizzard in 1948 isolated the village for 10 days, and a doctor had to be flown in to help a young girl stricken with glandular fever. That crisis jolted the 400 people of Ennis into a fund-raising campaign for a $56,000 clinic-hospital. The money came from card parties, rodeos, a minstrel show, a memorial fund, and auctions of donated goods—including one buffalo. Across the country, Mayor Ed Bouchey of Hillman, Mich., was telling his civic leaders: "Let's put the cart before the horse—build a clinic and doctor's home, and then look for a doctor." In one week $14,000 was raised. The Michigan Health Council's placement service brought in a doctor, to a band concert reception.



The Michigan Health Council's physician placement service brought a doctor to Hillman after this town of 439 decided to "put the cart before the horse—build a clinic and doctor's home, and then look for a doctor."

Fifteen businessmen in Platte, S. D., put up a total of $10,000 to buy a stucco house for conversion into a hospital. It attracted a physician, all right, but big opposition came from one man during a drive to raise $35,000 to remodel the place. He insisted a hospital was not needed. Then, in 1950, during a blizzard in the first winter after the hospital opened, his wife had to be taken there by sleigh for delivery of a baby. You can easily guess who led a second fund drive for that hospital.



Fifteen businessmen put up $10,000 to buy this stucco house in Platte, S. D., so they could convert it into a hospital—and thereby attract a physician to the doctorless community. No state or federal funds were sought.

The A. M. A. has been advising local medical societies to do more than merely name a community to physicians looking for a place to practice. And now many of those on placement lists receive detailed descriptions—even, as in the case of Indiana, lavishly illustrated brochures—describing the community as it will benefit their practice, their recreation hours, their worship, and their families. A special pitch is made to the doctor's wife, because many rural people have discovered the hard way that, if she does not like the town, her husband will not stay there for long.

It Is Happening Across the U. S.

All over the nation, with only few variations, the story is the same: The 300 people of Hookstown, Pa., seek help from the Medical Society of the State of Pennsylvania. They are urged to show that the town needs a doctor, to make the town attractive to him, and to be ready to help him. The advice works. A brochure mailed to names on a placement service list brings 16 physicians to look over an $18,000 home and clinic built with proceeds from a town fair, and one doctor stays. (Later, the same brochure invites industry to the town.) All schools and stores are closed for one day in Bertrand, Neb., so there can be a community auction to build a clinic. By the end of the day $7,000 is raised. Added to other campaign funds, this builds the clinic. A doctor comes to Bertrand. A 12-bed hospital in Salina, Utah, is not much use without a doctor. So all 1,700 people in town are alerted as greeters for physicians responding to placement lists of the A. M. A. and the Utah Medical Society. The one who stays is from far-off Norfolk, Va., Dr. Morris Fine.

Why all this fuss for a doctor? Why is it he cannot set up rural practice in an office of his own, on his own, without community help? The answers lie in modern medicine itself, and in its high standards. "The day of practicing out of the little black bag is gone with the horse and buggy," said Dr. W. W. White, who spurned big-city practice because he preferred the warm-hearted people whose 16-bed hospital attracted him to Faith, S. D.

While the cost of living in rural communities is less than in big cities, capital investment is higher because there are no group facilities used by many medical men. That is why a small town needing modern medical care finds it must pay for the facilities at the outset, rather than depend on ready cash of new doctors.

What ready cash? In years past, a sizable percentage of starting physicians came from well-to-do families. Now, more likely than not, they got their education through G. I. aid, or scraped an existence through medical school and then through the heavy loss-of-earnings period of internship. Only in a Hollywood film does the handsome young doctor pull into the sleepy little town on the 8:12 from Omaha, looking for a place to settle down. Until recently, the town mayor or the chamber of commerce president was getting on that train to plead at the medical school for a doctor. Now placement service is a better solution.

Through War And Peace

The service began during the last world war as an emergency aid for communities whose physicians were being called into uniform. Then returning doctors used the service to set up civilian practice. But as peace bloomed, both doctors and communities kept asking for the help. Here was a permanent thing. Youths just entering medical school were asking to get on the placement mailing lists. One first-year student from St. Louis took his parents to a community listed in Michigan. They liked it, and when he gets his degree next year he hopes to hang his shingle there. Not long ago, a visiting physician from Nigeria, Africa, gathered some community success story data on physician placement from A. M. A. headquarters in Chicago. He explained: "We have the same problem of distribution in my country."

The A. M. A. service is free, and there also is no cost or the service by 43 state medical groups. Any physician or medical student is eligible; A. M. A. membership is not required. And there is no charge to communities, either. Not all placement is for new physicians. Many doctors just want a change of scenery, like the woman orthopedic surgeon who has made at least three moves in recent years. She told the A. M. A. placement office: "I like to change my practice site every year."

Requests are forwarded by the A. M. A. to the medical associations of states preferred by the applicant. He then is mailed detailed listings of communities available. Each community on the list also gets the doctor's name for added contact. At last count there were over 1,000 pins on the A. M. A. wall map indicating physicians and communities trying to get together. This does not include hundreds more names and places on local society placement rolls compiled independently of the A. M. A. files. Many successfully placed physicians say they are as well off financially in rural areas as the average man anywhere in general practice. Actually, figures from the A. M. A. Bureau of Medical Economics and the U. S. Commerce Department show a higher average income from general practitioners in the towns than in the larger cities.

The Pioneers

The theory that community initiative is needed to revive medical service in America's hinterland was fostered chiefly in two states, Kansas and Virginia. The "Kansas Plan" was born after Dr. Franklin D. Murphy became dean of the University of Kansas medical school in 1948 at the age of 32. It was he who convinced communities that it is up to them to provide doctor facilities for rent or eventual sale. Dr. Murphy's model was Mankato, Kan. (population 1,532). The townspeople raised $13,000 in a few days, and soon a half-dozen physicians, lured by state society placement notices, were looking over the town, and being looked over. Dr. R. M. Owensby, who came to visit relatives in Mankato in 1949, stayed.

The plan of the Virginia Council on Health and Medical Care in 1946 was a pioneering kind of placement service. In the growth of a community spirit all across the state, Virginians were comparing clinic-building to churches for ministers and schools for teachers.

The Texas Medical Society spent three years making a survey that disproved what Executive Secretary C. Lincoln Williston last month described as "one of the half-baked ideas some folks still hold that a critical doctor shortage exists in the country today." What the survey did prove was that Texas had a physician distribution problem. In Texas, as in other states, physician placement services are going beyond the problem. Only now, as these new portraits of harmony between physician and rural community come into focus, are some authorities beginning to see more than just a close and needed relationship, more than a successful placement service.

Thomas Hendricks, Secretary of the A. M. A.'s Council on Medical Services, puts it this way: "When a doctorless community goes looking for a physician it primps itself up—and not just with a clinic. The people begin examining themselves and their resources in the light of his glance. They make sure their water and sewage systems are in good shape. They want the doctor's children to attend good schools, and so they put through their long-delayed school expansion program. Religion and churches benefit, too. The result is not merely a new doctor and a clinic. It is a better town, a better place to live—and that attracts more good families. When a community goes courting for a doctor, it is building itself up."

Atomic Warfare.—The trend of world events in the atomic age forces the inevitable conclusion that in future [we] must be prepared to care for mass casualties of a magnitude and abruptness which far exceed any previous experiences in conventional warfare. In planning to meet this challenge, the types and numbers of physical injuries to be expected can be reasonably estimated from the quantities of heat, blast, and radiation that will be unleashed by the atomic explosion. However, the effect of the psychologic trauma accompanying such a destructive weapon in producing mental breakdown or otherwise adversely influencing behavior is not so susceptible of measurement or prediction. Yet the emotional state of the relatively uninjured survivors in atomic attack is of primary consideration, because only by their efforts can there be prompt reorganization for lifesaving aid to and rescue of the seriously injured, or for any effective defense against an immediate enemy assault exploiting such a tactical situation.—Col. A. J. Glass, M. C., U. S. Army, Psychologic Considerations in Atomic Warfare, *United States Armed Forces Medical Journal*, May, 1956.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT TO THE COUNCIL

The Council has authorized publication of the following report.

H. D. Kautz, M.D., *Secretary.*

PRESENT STATUS OF THE TREATMENT OF TUBERCULOSIS

Col. James A. Wier (MC), U. S. Army

This report is the seventh in a series [1] by the Veterans Administration-Army-Navy group that has been studying the chemotherapy of tuberculosis since 1946. This report is largely a summary of the data presented at the 15th Conference on the Chemotherapy of Tuberculosis, held in St. Louis, Feb. 6-9, 1956. Its purpose is to briefly summarize data presented as a result of cooperative studies as well as to mention reports of pilot studies and other original work of individual hospitals or investigators. For more details on methods and techniques of the cooperative studies, reports of early conferences or the recent summary by Tucker [2] may be consulted.

This report is directed primarily toward the internist and general practitioner of medicine rather than toward the specialist in pulmonary disease or tuberculosis. No effort will be made to report on all papers presented or to interpret any of the more controversial material debated.

Three Basic Chemotherapeutic Regimens

Comparison has been made of 3,250 cases of pulmonary tuberculosis treated for at least four months with one of the three following regimens: 1 gm. of streptomycin given twice weekly plus 12 gm. of aminosalicylic acid (PAS, formerly para-aminosalicylic acid, U. S. P. XIV) administered daily; 1 gm. of streptomycin given twice weekly plus 0.3 gm. of isoniazid administered daily; or 0.3 gm. of isoniazid plus 12 gm. of aminosalicylic acid administered daily. These regimens, which were assigned to patients by random allocation, were continued for 12 months or longer in most instances. Results have revealed no differences regarding x-ray improvement or bacteriological conversion in patients with minimal pulmonary tuberculosis; however, in patients with far-advanced pulmonary tuberculosis, the bacteriological conversion rate at 5 to 8 months and at 9 to 12 months was significantly better in patients receiving isoniazid plus aminosalicylic acid than in those receiving either streptomycin plus isoniazid or streptomycin plus aminosalicylic acid. In these cases, the streptomycin was administered twice weekly. The streptomycin-isoniazid combination produced slightly better results than the streptomycin–aminosalicylic acid combination in the far-advanced cases. Careful evaluation of results and personal experiences of all investigators supported the belief that roentgenographic improvement per se was the least important means of evaluating results of drug therapy, particularly in more advanced and cavitary disease. It was felt that evaluation of cavity closure and bacteriological conversion and eventual relapse rates would be the most reliable guides.

In the evaluation of cavity closure, differences in results with these three regimens were least apparent in patients with small cavities. In patients with cavities no larger than 1 to 2 cm. in diameter, the percentage of cavity closure at 12 months without use of resectional surgery was the same with streptomycin plus isoniazid and isoniazid plus aminosalicylic acid, but only slightly lower with streptomycin plus aminosalicylic acid. In patients with cavities of 2.5 to 3.5 cm., the combination of isoniazid plus aminosalicylic acid was slightly more effective than the other regimens; in patients with cavities larger than 4 cm. in diameter, the isoniazid–aminosalicylic acid combination yielded a significantly higher percentage of cavity closure at 12 months than did the other two regimens. The streptomycin–aminosalicylic acid combination proved least effective. This superiority of isoniazid plus aminosalicylic acid was apparent at each evaluation period.

Bacteriological resistance to streptomycin (equal growth in 10 mcg. per milliliter in vitro) did not differ significantly in the groups treated with streptomycin-isoniazid or streptomycin–aminosalicylic acid. A different picture was presented, however, concerning isoniazid resistance (equal growth in 5 mcg. per milliliter in vitro). There was a significantly higher incidence of patients with organisms resistant to isoniazid when they were treated with streptomycin plus isoniazid than when they were treated with isoniazid plus aminosalicylic acid. This became more apparent at each observation period after four months and was more striking in patients with cavities larger than 4 cm.

In summary, it may be stated that the combination of isoniazid plus aminosalicylic acid was significantly more effective than either of the other two regimens in the treatment of pulmonary tuberculosis, especially in those patients with more advanced disease; in less extensive disease there was no significant difference between the regimens.

Pilot Studies

Triple Drug Therapy.—Two hundred eighty patients were treated for at least eight months with a three-drug combination, streptomycin plus isoniazid plus aminosalicylic acid, as compared to a streptomycin-isoniazid combination or streptomycin plus aminosalicylic acid. Results showed little difference, except that there was more bacteriological conversion at all evaluation points with the first two combinations. The streptomycin was administered twice weekly in all the combinations.

Streptomycin Administration.—Preliminary results in treatment of 142 patients would tend to confirm the British Medical Research Council studies,[3] which demonstrated that administration of 1 gm. of streptomycin plus isoniazid, both given daily, produces less

---

From the Fitzsimmons Army Hospital, Denver.

emergence of organisms resistant to isoniazid than administration of 1 gm. of streptomycin twice a week and isoniazid daily.

Duration of Chemotherapy.—Results of cooperative study comparing the effectiveness of treatment in patients receiving 6 or 12 months of drug therapy after achieving x-ray stability, cavity closure, and bacteriological conversion have been inconclusive. All investigators were in general agreement that drug therapy should be continued for at least a year in all cases and for no less than six months after the achievement of clinical control of the disease as defined previously. Chemotherapy of longer duration should be used in patients with more extensive disease and with so-called open-healed cavities.

Bed Rest.—Cooperative studies to evaluate the need for bed rest have been largely inconclusive. One Veterans Administration hospital has treated all patients for several years on a liberal basis of free activity within the hospital. Their results in a group of 200 patients compare favorably with the over-all results reported from other Veterans Administration hospitals. One Army hospital has established a program to evaluate the importance of modified bed rest as compared to ad libitum ambulation in hospitalized patients. A preliminary report indicated no differences in the results in 95 patients on bed-rest therapy and in 80 patients permitted early ambulation. It was emphasized by all concerned that preliminary hospitalization of tuberculous patients was indicated and initial home care was not recommended, even though it appears feasible to shorten the duration of hospitalization in most patients undergoing original drug treatment.

Individual Drugs

Pyrazinamide.—In 1954, at the 13th Veterans Administration Conference, there had been concern over the use of pyrazinamide because of an apparently high incidence of toxic effects on the liver; however, its effectiveness in animals, when combined with isoniazid, and the results of therapeutic trials in humans, have reawakened more widespread interest in this drug. It has been found that combined pyrazinamide-isoniazid therapy is effective in patients who have never received either drug before. A preliminary report at this conference, on a relatively small number of cases, indicated that this two-drug combination (137 patients treated) was somewhat more effective in bringing about x-ray improvement, bacteriological conversion, and cavity closure than were streptomycin plus isoniazid (78 patients), isoniazid plus aminosalicylic acid (112 patients), or streptomycin plus aminosalicylic acid (115 patients). In all studies reported there is a significant factor of toxic effect on the liver; approximately 10% of the patients receiving pyrazinamide showed abnormal results in liver function tests, and about 3% showed frank jaundice. Most of these conditions, however, revert to normal when the drug is withdrawn. One exception to the reported toxic effect on the liver was in the group of patients previously reported by the Public Health Service, in which the rate of toxicity was much lower. The combination of pyrazinamide plus isoniazid also was effective in patients with organisms resistant to streptomycin and/or aminosalicylic acid. Pyrazinamide alone may be used with reasonable success for periods of 30 to 60 days to cover surgery in patients resistant to other major drugs. Pyrazinamide plus viomycin was believed to produce no better results than those expected with pyrazinamide alone.

Cycloserine.—The effectiveness of cycloserine in the treatment of pulmonary tuberculosis has now been investigated for about two years. A preliminary report on cycloserine alone versus combined isoniazid-aminosalicylic acid therapy has established that cycloserine alone is inferior to this combination in all respects evaluated. Schmidt reported that cycloserine and isoniazid appear to act synergistically against tubercluosis in the monkey. Preliminary clinical reports by Epstein indicate that cycloserine plus isoniazid may be an effective regimen in man. Reports of toxicity, particularly to the central nervous system, have continued This toxicity appears to be related to blood levels of the drug and is higher with levels over 30 mcg. per milliliter. There has been no indication of increased toxicity from the combined use of cycloserine and isoniazid.

Hinconstarch.—A combination of amithiozone, isoniazid, and starch was studied in experiments with animals. It was felt to be about as effective as the amithiozone and isoniazid contained in the combination might be individually, although there was some indication that the toxicity of amithiozone was lessened in the starch combination.

Isoniazid.—Isoniazid is degraded in human subjects into several derivatives, one of these being biologically inactive acetylisoniazid. It has been shown that the degree of this inactivation may vary significantly from individual to individual. The usual chemical assay method (Poet and Kelly) for determining the isoniazid level in serum does not distinguish between the active free isoniazid and the biologically inactive derivatives. As a consequence, some individuals with adequate serum levels determined by the chemical method will have an entirely inadequate level as determined by the bioassay methods, indicating that in these individuals there should be little therapeutic effect from the isoniazid used. Variations of free isoniazid in the urine reflect the free (biologically active) isoniazid in serum. In some of these individuals the simultaneous administration of aminosalicylic acid will elevate the level of biologically active isoniazid in the serum, probably by competing for the acetylation mechanism.

Thoracic Surgery

Surgical Resection.—Consolidated data presented at the conference indicated that 1,307 pulmonary resections were done during the last year. The percentages of types of operations for 1954-1955 were pneumonectomy, 5%; lobectomy, 39%; and segmental and wedge resection, 56%. Mortality rates for these procedures were pneumonectomy, 21%; lobectomy, 4%; segmental resection, 1.3%; and wedge resection, none. The overall rates of mortality for the period 1953 to 1955 inclusive were pneumonectomy, 16.5%; lobectomy, 3.3%; segmental resection, 1%, and subsegmental resection, none. The rate of serious complication as evidenced by empyema was pneumonectomy, 18 5%; lobectomy, 4 7%, segmental resection, 4%; and subsegmental resection, 0 8%. The incidence of complication is higher in the patient previously treated, but with tubercle bacilli still susceptible to the drugs being used, than in a patients receiving treatment for the first time; complications are most frequent in patients previously treated whose tubercle bacilli are drug resistant.

Resection of Closed Lesions.—One Veterans Administration hospital reported on a follow-up of patients with pulmonary tuberculosis with closed lesions in whom surgical resection or medical treatment was administered by random selection. Four of 43 patients in whom resection of closed lesions was added to medical treatment had relapses; 3 of 56 in whom resection was not done had relapses. In general, an increasing lack of enthusiasm was noted among the investigators for resection of closed necrotic lesions in patients receiving adequate chemotherapy.

Morphology and Bacteriology of Closed Lesions.—Data from the cooperative study were presented on bacteriological examination of 1,367 surgically resected lesions, of which 64% were closed lesions, 13.5% were open lesions, and 22 5% were mixed. Seventy per cent of the closed lesions were negative for tubercle bacilli by culture, whereas 40% of the open and 44% of the mixed lesions were negative. It was noted that, the larger the closed lesion, the higher the percentage of bacteriological positivity, and the longer the period of preoperative chemotherapy, the fewer the number of positive lesions. The duration of preoperative chemotherapy seemed to have no relation to the percentage of positivity of open lesions.

Nonpulmonary Tuberculosis

Miliary and Meningeal Tuberculosis.—The favorable trends noted with miliary and meningeal tuberculosis reported previously are continuing. A two-year follow-up has revealed 95% survival of patients with miliary tuberculosis treated with streptomycin-isoniazid, with or without aminosalicylic acid, the two-year survival rate in patients with meningitis similarly treated is 80%. Most of these patients have received triple therapy, but all have received isoniazid and streptomycin. These results are significantly better than were accomplished previously with a combination of streptomycin and aminosalicylic acid.

Genitourinary Tuberculosis.—One investigator, expanding on the results of chemotherapeutic regimens in genitourinary tuberculosis, indicated that triple therapy has shown about 5% better results than any combination of two drugs. He again emphasized the trend toward less surgical intervention in renal tuberculosis. He recommended that drug therapy for most cases of renal tuberculosis be continued for at least 24 months

Some Special Problems

The Open-Negative Tuberculous Cavity.—The open-negative tuberculous cavity is defined as an empty space lined by hyalinized connective tissue with no sign of specific inflammation in the wall and with no exudate in the space. Ninety-eight surgically resected cavities were examined. Twelve showed open healing on pathological examination; 55 cavities were active clinically, and on pathological examination 31 were clinically open-healed with negative preoperative bacteriology. Of these clinically open-healed cavities, two-thirds were active on pathological examination. Only 4 of 12 open-healed cavities (pathologically) had typical thin-walled appearance as evidenced by a preoperative x-ray. In some instances, patients with open-healed cavities were treated with streptomycin plus aminosalicylic acid, indicating that this phenomenon is not necessarily the result of treatment with isoniazid as has been suggested.

The in Vitro Action of Antituberculosis Agents Against Multiplying and Nonmultiplying Organisms.—Further evidence was presented that indicated that both streptomycin and isoniazid are most active against tubercle bacilli that are actively multiplying and that they have little effect on those that are not multiplying or are in a resting state.

Summary

As data accumulate on large numbers of patients with pulmonary tuberculosis treated with long-term combined chemotherapy, it is increasingly evident that most patients undergoing an initial course of therapy do well on any of the adequate drug regimens. Significant differences occur only in patients with far-advanced disease who are selected on the basis of large cavities or multiple bilateral cavities. In these cases the best results have been obtained when isoniazid and aminosalicylic acid are given daily in combined therapy. These findings suggest that no rule of thumb can be dictated that will apply to chemotherapeutic treatment of all patients with pulmonary tuberculosis. In these problem cases, other factors are arising that further complicate the proper treatment of the individual. These include the different rates of inactivation of the chemotherapeutic agent in the patient being treated, the significance of the open cavity remaining in a patient who is always bacteriologically negative, and the development of resistance of the bacterial organisms to the chemotherapeutic agents used.

FURTHER PROGRESS IN SPECIFIC THERAPY OF TUBERCULOSIS

GUEST EDITORIAL

H. Corwin Hinshaw, M.D.

Each year some hundreds of physicians and surgeons gather to learn the latest results and opinions concerning specific drug therapy of tuberculosis as revealed at the Conference on Chemotherapy of Tuberculosis, sponsored by the Veterans Administration and the armed forces. A report to the Council on Pharmacy and Chemistry concerning developments in this field as reported at the 15th conference appears elsewhere in this issue of The Journal (see page 471). This continuing cooperative project, surely the largest in the history of medicine, has involved more than 50 hospitals and at least 15,000 patients. In addition to supplying factual data and a digest of opinions to physicians everywhere, this conference constitutes a powerful educational force within the VA and the armed forces. Never before has it been demonstrated so well that unique research opportunities in the federal services are offered to physicians with a scholarly bent.

The accumulated data convince me that several almost equally effective therapeutic regimens have been established by this great research project. The superiority of aminosalicylic acid combined with isoniazid is demonstrated only by statistical analysis of extensive data, for any margin of superiority is slight and seems to apply only to bacteriological results. In other respects no convincing difference is observed between several of the regimens studied. To the practicing physician this appears to indicate that any one of the various combinations of streptomycin, isoniazid, and aminosalicylic acid may be used with confidence. Often the individual patient's tolerance and comfort will be the deciding factor in the choice of therapeutic regimen. Furthermore, what is best for the statistical "average" case may not be best for the individual. Thus, an appeal is being made for clinical judgment in choice of therapy rather than for adherence to protocol. Such judgment is employed by the very capable physicians in government service; the patients selected at random for research constitute a minority of those treated in many institutions.

Attention is directed to the observation that daily administration of streptomycin again appears to offer advantages over twice-weekly administration when this drug is combined with isoniazid. This fact, shown recently by British observers, does not necessarily conflict with earlier conclusions of the VA-armed forces project, because the latter work was done before the discovery of isoniazid and conclusions apply to combinations of aminosalicylic acid and streptomycin only. The toxicity of streptomycin when administered daily has often been exaggerated and is now diminished by the use of streptoduocin, a mixture of dihydrostreptomycin and streptomycin. Studies are under way in some civilian institutions to determine if streptomycin given every 48 hours will have a sustaining antibacterial effect comparable to that of streptomycin given daily.

Finally, I must contradict the popular impression that tuberculosis therapy has become a standardized routine. Each of these great conferences brings to light more problems than are solved. Intense efforts are being expended to further shorten the period of hospitalization and to lessen the hazard of relapse. If these are successful, every taxpayer will benefit, as well as the patients involved, for tuberculosis continues to be the most costly and devastating of the chronic infectious diseases in the United States and throughout the world.

Clinical Professor of Medicine, Stanford University School of Medicine, San Francisco.

PORTRAITS IN HARMONY

When a community puts on its Sunday best to woo a doctor into its fold, that is a love story. But it is more than that. Elsewhere in this issue (page 468) is an article entitled "Portraits In Harmony." It is the story of how local medical societies, through their placement services, are helping rural areas reverse the trend of general practitioners going to big cities. The towns are doing this by campaigning for contributions and investments, and by donating time and labor to create the one thing most young doctors cannot afford outright: facilities to meet the demands of modern medicine. The doctor is not given a handout; instead he properly and willingly pays for his clinic in rent or gradual purchase. These efforts are building communities—and thereby building America.

MEDICINE AT WORK

Elsewhere in this issue (page 468) is a section entitled Medicine at Work. This is a new column, beginning with this issue of The Journal, which will be published from time to time and which will feature attempts of the medical profession and other groups interested in health to solve medical problems facing this nation. The American Medical Association has many committees and councils organized to help meet these problems; so do other organizations. Much also is done by civic-minded groups and individuals, as is told in the story "Portraits in Harmony." Too little, however, is known of such efforts, and, as a result, often there is criticism because of lack of information when there should be commendation because of actions taken. It is hoped that this reporting will permit members of the A. M. A. to be better informed about what their organization is doing and about what other groups are attempting to accomplish in the health field. It is also hoped that the information will be shared with all, whether they are physicians or not, who have a genuine interest in meeting the medical needs of this nation.

LONG-RANGE EFFECT OF EXPOSURE TO RADIATION

Because of the wide publicity given to conflicting statements, there has been much confusion in the public mind regarding the long-range effects on the human race of exposure to various ionizing rays. The statements that atomic explosions caused no damage to descendants of the people in the bombed cities of Japan on the one hand and that atom bomb testing has already seriously undermined the genetic basis of all mankind on the other present extremes, both of which are in error.[1] It is important that the truth be recognized. All radioactive materials, whether naurally occurring radium or artificially produced isotopes, emit rays, the most important of which from a genetic standpoint are gamma rays. In emitting such rays these elements undergo a process of decay or transformation into a more stable form. X-rays used chiefly for medical diagnostic purposes may also, by their scattered radiation, provide a significant amount of genetic damage. The effects of the radiations to which we are all exposed have been intensively studied by several committees of the National Academy of Sciences, and two reports that give the most authoritative views now available have been published.[2] These are worthy of wide dissemination. As with most things on earth, processes involving radiation are neither good nor bad in themselves. When properly understood and handled they may be made to serve man in useful ways, but like fire and electricity their potential dangers must be known and appropriate precautions must be taken when they are so used.

A certain amount of radiation, emanating from cosmic rays and other natural sources, has always been present in our environment. This is called background radiation, and it is estimated that in 30 years the average dose to which the gonads are exposed is between 4.3 and 5.5 r, depending on the altitude at which a person lives, because the exposure is greater at higher altitudes. The period of 30 years is chosen because most children are born before their parents are over 30 years old. It is further estimated that in the first 30 years of life the average exposure from diagnostic x-rays is about 3 r. Radioactive fall-out from testing atomic weapons, if such testing were to be carried on at the present rate, would give an average 30-year exposure of about 0.1 r, although estimates vary from 0.02 to 0.5 r. In any case, as compared with that from diagnostic x-rays, it is small but nevertheless significant.

Genes are present in all body cells, and mutations in these genes may be produced by heat, chemical action, or radiation. Such mutations are of significance only when they involve the reproductive cells. A certain amount of mutation has always taken place as a result of background radiation, but every added source of radiation increases the chances for additional mutations. Mutant genes are usually recessive, so that for maximal effect they must be present in both parents, but even in the dormant stage they are carried along from generation to generation. They almost always lead to some harmful effect, so that the offspring inheriting the new characteristic may be stillborn, be so handicapped as to be unable to survive, be unable to reproduce, or be handicapped for life with a defect that shortens life or reduces fertility. Thus the more harmful the mutant gene the sooner it dies out when natural selection is allowed to exert its evolutionary force. Modern medical science, however, tends to salvage many of these handicapped persons and to retard the natural extinction of their kind.

Geneticists are now agreed that, although certain levels of exposure to radiation are alarmingly dangerous, there is no such thing as a safe level because all radiation from whatever source is potentially dangerous from the genetic viewpoint. Because the disabilities and deaths due to radiation-induced mutations are spread out thinly over many generations, the cost in human life and happiness is difficult to measure and the individual sufferers cannot trace their trouble to its exact source. With these facts in mind, certain recommendations can be made. A system should be set up whereby every person will keep a record of his exposure to x-rays throughout his entire life. The use of diagnostic x-rays should be held to a minimum consistent with sound medical diagnosis and care, and greater efforts should be made to shield the gonads, especially in patients under 30 years of age. The radioactivity of our natural environment should be kept under constant review. Should special circumstances arise where greater exposure than the permissible level is required for one or another purpose, persons not likely to have any more children had best be assigned. Protective devices have been built into atomic installations consistently, and this trend must be continued both in them and in research laboratories. Furthermore, more convenient means than those now available must be found for disposing of radioactive wastes from such installations. All risks attendant on the use of atomic energy must be carefully weighed against the expected benefits. In the solution of some of these problems a beginning has been made. There are, however, still potentially dangerous gaps in our knowledge, and filling these gaps is a matter of the utmost urgency.

PROCEEDINGS OF THE CHICAGO MEETING

ABSTRACT OF PROCEEDINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION AT THE ANNUAL MEETING IN CHICAGO, ILL., JUNE 11-15, 1956

The actions of the House of Delegates at the Chicago Meeting are herewith abstracted so that the readers may have this information in digest form. The official proceedings will be made available, as in the past, in a booklet, which will be sent to all members of the House of Delegates and officers of the American Medical Association by the Secretary. This booklet will not be available for several weeks.—ED.

Preliminary Report of Reference Committee on Credentials

Dr. Raymond F. Peterson, Chairman, Montana, reported that 192 delegates of a possible 196 had been qualified and seated, and the Speaker, Dr. E. Vincent Askey, announced that a quorum was present.

Invocation

The Very Reverend James M. Maguire, President of Loyola University, pronounced the following invocation:

O God, we pause at the opening of this national convention of physicians to acknowledge gratefully and filially Your omnipotence, Your sublime holiness, and, in a special way, Your loving kindness and care for Your children. From the deep natural instincts that You have implanted in the hearts of earthly fathers and mothers, we know that You, Who art father of us all, look upon a good done to one of Your children as a service of love and devotion even to Yourself. How deep, then, must Your love be for the physician who goes about ministering to the ills and assuaging the pain of Your children. Grant, O heavenly Father, to those who minister to the afflicted body a deep realization and a constant awareness of the infinite value of the human soul that gives form and life to the body. May their ministrations for the life and health of the body always assist the patient on his way You, his eternal Father in heaven. Amen.

eport of Reference Committee On Rules and Order of Business

Dr. Herbert H. Bauckus, Chairman, New York, presented the report, which was adopted:

eference Committee on Rules and Order of Business (1) that the Speaker be authorized to vary the of business if necessary adjustments become evident, un- s such changes are objected to and otherwise ordered by the House; (2) that the list of seated delegates as certified to the Secretary by the Credentials Committee shall constitute the official roll call and record of the House attendance; (3) that the Speaker be allowed to grant the privilege of the floor to such persons as may be presented by the President or Chairman of the Board of Trustees and to others who will aid in the deliberations of the House; (4) that the Speaker recess the House at times to be determined by him best suited for the comfort of the House members unless countermanded by the vote of the House.

Address of Dr. Lowell T. Coggeshall

Dr. Lowell T. Coggeshall, Special Assistant for Health and Medical Affairs, U. S. Department of Health, Education, and Welfare, was introduced by the Speaker, and delivered the following address:

Mr. President, Members of the House of Delegates of the American Medical Association, Officers of the Association, and Guests: It is indeed a very pleasant assignment to appear before you this morning in behalf of Secretary Folsom who wished to come, but the pressure of other matters has prohibited his attendance here as it has on many other similar matters. It is an especially pleasant task to appear before you because I am somewhat in the position of the hometown boy coming back home. I might say, parenthetically, that there are many times in Washington I wish these tasks would come a little more often, but there doesn't seem to be a satisfactory substitute for the business at hand. I know you have a very crowded agenda and lots to do, and I am not going to appear before you long. I have no prepared speech. I am reminded of a remark of Secretary Wilson the other night. Speaking about prepared speeches, he said, "From now on, I am going to write my own speeches so that I will be dead certain when I find a foot in my mouth that I will know whose foot it is." So, if I have a foot in my mouth this morning, I shall know for certain whose foot it is.

I would like to report to you more as a member of your organization, rather than as a representative of the government in Washington, about how things are going in Washington as seen from a very busy schedule in the past few months. I accepted this assignment rather reluctantly, not to minimize the importance of the task, because I believe the Secretary's position in medicine is probably the single most important position held by any one man today. The potentialities for good and the potentialities for harm are equally present. I have had a very pleasant experience, however, in Washington on the whole. Primarily my pleasant experience stems from the association with this organization. I was told when I went down there that I should have my head examined for accepting the post. I did not believe it was true then; I do not believe it is now. I was told that you got little credit for anything good that was done, they expected you to do better, and you got all sorts of blame for everything that went wrong. I would like to thank particularly the members of the American Medical Association, the Liaison Committee, and the Legislative Committee.

The policy of the Department of Health, Education, and Welfare at this time is one of an open door. We solicit opinions and we attempt to evaluate those that are presented to us, and they are multiple as you can be assured. There are certain positions that we have to take and that you would expect one of your representatives to take in relation to the over-all progra that may not be entirely consonant with the thinking of t organized body of this Association. On the other hand, I wish to assure you, with conviction and sincerity, that the over-all objectives of the Department of Health, Education, and Welfare, as they apply to the practice of health and medicine in this country, do not vary from the objectives of this organization.

It is particularly pleasant for me to tell you that I am working with Secretary Folsom, one of the most forthright, intelligent noncompromising individuals that I know of. His guide line is, will it be best for everyone concerned? In saying that, I am sure I express the sentiments of many others who come in contact with him.

First, may I point briefly to the over-all task. The Department of Health, Education, and Welfare is a very complex organization simply because it has in it the many facets, the many organizations, that have more or less existed independently. Into this organization come the three primary functions, namely, the function of health, of education and of welfare. Mr. Folsom is an expert in the field of welfare; Mr. Harold Hunt, former superintendent of schools in this city, is primarily concerned with education, and I have the responsibility of advising the Secretary on matters of health.

In this particular organization, as far as the government is concerned, is the enormous department of the Public Health Service. I do not know whether any of the members of the Public Health Service are here this morning, but may I say to you that my admiration and respect go to them as a very dedicated group working to the best of their ability, and they merit your full support. Let us take, for example, the poliomyelitis situation, one of the most dramatic, most emotional situations that has appeared on the scene in the past few years. After seeing it from the inside, I am not surprised at the furor in connection with the distribution of this vaccine. I am surprised that it wasn't worse. I am happy to report to you today that June will probably result in the largest release of this vaccine that has occurred in any month. The Public Health Service has been guided very carefully by its technical experts, including Dr. Salk, and has heeded their advice. By another year, we hope to be out of the vaccine distribution business entirely, putting it on the same basis as any other beneficial vaccine now available. I would like to say at this time that the more children we can get immunized in the forthcoming weeks, the better off we shall be. There was every reason for the program to go wrong, as I say. I am reminded of my short stay in Ann Arbor early in the war when they built the Willow Run plant. Everything was wrong—transportation was not available, there was no housing, there was no food, the labor market was not there, everything was wrong; but less than a year from the day it was started, bombers were rolling off at the rate of one an hour. People have criticized the poliomyelitis program from the standpoint of its statistical evaluation, distribution, and everything else. However, the end-results coming today from Texas, Washington, Rhode Island, and Florida show that there is about an 80% reduction in the number of paralytic cases of poliomyelitis already this year. These are not isolated instances

To go on very quickly, I would simply close by saying that we are primarily concerned at this time with legislative matters. Of particular interest to this group is the bill S. 7225 that all of you are so much interested in. Here, as you know, the Secretary took a very forthright position, studied the matter thoroughly from all its aspects and made his decision that he was opposed to this for the reasons that have been well known to you. In this respect, I think you cannot and never will understand the pressures that were exerted to have a contrary opinion expressed. We are not happy about some of the turns of events there in lowering disability when everything is being done to improve the working conditions for man and extending the longevity of his working period. But there are certain compromises that will be made in spite of everything.

I would point out to you, which you probably know, that the attitude in Washington, particularly in the House and Senate, is that health is the most wonderful thing in the world and we do not support it sufficiently. I will give you one short example of that. Last year the operating budgets for the National Institute of Health were 102 million dollars. The Secretary, with the advice of the people in the National Institute of Health, outside scientists, medical deans, and many others, thought that an increase of 15 million dollars that was rationally worked out would be to our best interest. This came up before the Appropriations Committee of the House and the budget was hiked another 9 million dollars, from 102 million to 126 million dollars. Then the House made it up to 135 million. When it got into the Senate, it was pointed out that there was lack of imagination in the Department of Health, Education, and Welfare, there was no foresight, and, said they, "You do not know how much money needs to be spent, and we are going to hike it to 182 million dollars." This was done, an increase of 82% in one year. This will be cut back, but I only draw it to your attention to indicate the attitude of the present Congress.

It is our attitude in the Department of Health, Education, and Welfare—and I would not stay there five minutes if it were not so—that we must improve the health of the people by doing those things that are healthy, that we must give more to rehabilitation rather than make more attempts to get people on various pension plans or other subsidies. More attention should be given to occupational hazards, because we are going into increased occupational hazards as we become more and more industrialized. We must concern ourselves with the health aspects of radiation energy.

All these things are highly essential, and we are not trying to put the government in the business of running medicine. For any of you who are concerned that inside the government at the present time there is an insidious movement in this direction, I can assure you with every conviction and sincerity that just the opposite is true.

Finally in closing, again I would like not only to pay my respects but to give my thanks to the Washington Office of the American Medical Association, Dr. Tom Alphin, and his associates. They have been very ready to express their view, the position of your organization. There has been no attempt to pressure. The office in Washington and the headquarters office of the Association have been most helpful.

As I have said, in spite of the opinions that I received before I went to Washington, I accepted this post, although with some reluctance, but the experience has been very pleasant and just the opposite of what I had been told it would be. I hope that my services in Washington will be evaluated more on the basis of the job that I do rather than the speeches I give. Thank you very much!

Resolution Regarding President Eisenhower

Dr. James Z. Appel, for the delegation from Pennsylvania, presented the following resolution:

> *Resolved*, That the House of Delegates of the American Medical Association, sitting in annual session in Chicago, Illinois, this 11th day of June, 1956, wishes to express to Dwight D. Eisenhower, President of the United States, its happiness on his present favorable progress toward recovery from his recent serious illness and its sincere hope for a rapid return to complete and robust health.

Dr. Appel moved, and the motion was seconded by several, that the resolution be adopted and that a copy of it be forwarded to the President of the United States over the signatures of the President of the American Medical Association and the Speaker of the House of Delegates. The Speaker received the unanimous consent of the House for the resolution to be considered at once without referral to a reference committee, and the House unanimously adopted the resolution and Dr. Appel's motion.

Citation to Dr. Carl M. Peterson

Dr. Ross T. McIntire of Chicago, former Chairman of President Eisenhower's Committee for Employment of the Physically Handicapped, was given the privilege of the floor for the presentation, posthumously, of a citation to Dr. Carl M. Peterson, late Secretary of the Council on Industrial Health of the American Medical Association.

The citation, in the form of a memorial plaque, was read by Dr. McIntire as follows:

The President's Committee on Employment of the Physically Handicapped Honors Posthumously Carl. M. Peterson, M.D., for a lifetime dedicated to the increased health, welfare and employment opportunity of his fellowman. As Medical Committee Chairman of the President's Committee, he labored long to bring the concept, "Ability Counts, not Disability," to all members of the medical Profession.

As Secretary, Council on Industrial Health, American Medical Association, he was the pivot around which many of the great advances in industrial medicine centered in the past two decades.

As a man, a physician, an administrator, a friend, husband and father, he impressed all with his vigor, fairness and vision. Our country and her handicapped men and women of today and tomorrow have much for which to thank this tireless man whose untimely death in the performance of duty saddened all those who knew him.

The Executive Committee of the President's Committee has authorized this Testimonial to their departed member, and the Medical Committee has caused it to be inscribed for presentation to and permanent retention by the American Medical Association.

Edward C. Holmblad, M.D. Chairman, Medical Committee

Melvin J. Maas, Chairman President's Committee

The plaque was accepted on behalf of the American Medical Association and its Council on Industrial Health by Dr. William P. Shepard, Chairman of the Council.

Contribution to American Medical Education Foundation

Dr. F. Lee Stone, President of the Illinois State Medical Society, presented to Dr. Elmer Hess, in the absence of Dr. Louis H. Bauer, President of the American Medical Education Foundation, a facsimile check from the Illinois society to the Foundation in the amount of $164,940.

Dr. Harold M. Camp, Secretary of the Illinois State Medical Society, explained to the House the facts behind the contribution, as follows:

Mr. Speaker and Gentlemen of the House: During the past three and one-half years, since an allocation of $20 from each member's dues has been given to the AMEF, the Illinois State

Medical Society has given a total of $678,680 for medical education. In addition to the check which has just been presented, as of June 1, 1956, there will be additional payments during the remainder of this year which will bring the total for 3½ years from dues from members to above $700,000. We have been informed that this amount represents more than 12% of all the monies contributed from every source through the AMEF.

Adoption of Minutes of Boston Clinical Meeting

The minutes of the Clinical Meeting held in Boston, Nov. 29-Dec. 2, 1955, were adopted as printed and distributed to the members of the House of Delegates.

Distinguished Service Award to Dr. Walter L. Bierring

Dr. Gunnar Gundersen, Chairman, Board of Trustees, presented the names of three physicians selected by the Board from the list of nominations for the Distinguished Service award, so that the House of Delegates might elect one to receive the award. The nominees were Dr. Walter L. Bierring, Des Moines, Iowa; Dr. Emil Novak, Baltimore; and Dr. Tom Douglas Spies, Birmingham, Ala. Dr. Bierring was elected recipient of the Distinguished Service award of the American Medical Association for 1956.

Remarks of President of American Medical Education Foundation

Dr. Louis H. Bauer, President, American Medical Education Foundation, addressed the House as follows:

I am sorry that I was not in the House when the presentation of the check from the Illinois State Medical Society was made. I think you will agree that it is a very large check in more than one sense. I would like you to know that today's gift includes monies received from the Illinois society for a total of $650,000 since 1953 and, added to this, specialty medical groups and the woman's auxiliary within that state have contributed another $118,000. The total amounts contributed to medical schools from both the Foundation and the National Fund for Medical Education since they were started is something over $9,500,000, of which the American Medical Education Foundation has given $4,600,000, and of the amount which has come to the Foundation, 12% of it has come from the Illinois State Medical Society. I think that is something that might make the rest of you sort of hang your heads. I do not know of any group that has gone all out the way Illinois has from the start. There are some other states that are coming along now, too, but it certainly gives us a goal to shoot at, and I think that everybody in this House, everybody in the medical profession, and certainly everybody in the medical schools owes a tremendous debt of gratitude to the Illinois State Medical Society, which has pioneered in the contributions and has gone out ahead of everyone else in making these funds available for the freedom of medical education.

I have here an Award of Merit from the American Medical Education Foundation to the Illinois State Medical Society for outstanding contribution to the preservation and continuation of the high standards of medical education in the United States of America, and I should like to present this to Dr. Stone and Dr. Camp, if they would come up here to receive it.

Dr. Stone accepted the Award of Merit with an expression of appreciation.

Address of the Speaker, Dr. E. Vincent Askey

The Speaker presented the following address, which was referred to the Reference Committee on Reports of Officers:

We have endeavored, at each meeting of the House, to call attention to a few parliamentary considerations with which we all should be familiar.

We have found that most misunderstandings arise because of really minor details. Rules are rules and should be followed—as a rule. However, by martinet-like stickling to form rather than intent we may defeat the best interests and desires of the majority. Hence, some leniency in interpretation is always wise unless the rights of others are jeopardized. Firmness is in order when basic rights are in danger or violated with injustice.

A motion is never carried until announcement of the vote by the Chair has been made. You will notice that your Speaker always waits a reasonable time after the vote before announcing the result. This is deliberate and sometimes is due to question as to the result. It allows time for a request for a division call. At other times it is to allow a member to record or change his vote. At other times it is to allow a member to reopen the discussion if he has found something important and if he is entitled to the floor. If discussion is reopened, then the whole vote must be retaken as some members may have changed their minds. No member can be expected to vote until his mind is satisfied completely unless discussion has been limited or closed by a two-thirds vote and the previous question called. If the result of the vote has been announced then discussion is ended and can be reopened only by motion to reconsider or to rescind. A motion to reconsider can be made only by one who voted on the prevailing side because our Bylaws direct us to follow Robert's Rules of Order. Some courts of law have held that where no specific rule is stated in the Bylaws any member may move reconsideration. Robert's Rules, we believe, constitute that specific rule in our case. A motion to rescind needs a two-thirds vote to carry unless notice has been given.

Appeal from a decision of the Chair may be made on any ruling which is one of opinion but not a matter of fact, such as a stipulation in the Bylaws. Appeal cannot be made, however, if other intervening business has been transacted. Appeal must therefore be made promptly or not at all.

In my letter to you you will remember I discussed somewhat the procedure of introduction of reports and new business or resolutions. Two main matters of business are considered by the House, exclusive of the stated addresses of officers and the routine of elections and similar procedures. These are:

(1) *Previously Considered Items.*—These are matters which have been before the House previously and have been referred to some committee for study and report or to the Board of Trustees for study and report or action. Also included are other matters which have been considered by the Board of Trustees since the last meeting of the House and which it is deemed wise to report to the House. These are official committee reports or supplementary reports of the Board of Trustees.

Matters described under category (1) will be allowed to be presented by the Chairman, or designated individual, in detail as deemed necessary by that Chairman. (Chairmen are cautioned that they will not be popular with the House if they do not use good judgment in briefing their presentation.) After presentation, assignment to the proper reference committee will be made. Debate before the reference committee will then be in order.

(2) *New Items for Consideration.*—These are matters which, as such, have not been before the House and are a priori approaches to problems brought to the House by individuals or delegations of members. These are our resolutions.

There was some criticism from the last meeting, constructive criticism, and I wrote to you and asked that you send it, and I appreciate your feelings in these cases. I feel that perhaps I rushed the resolutions through a little bit fast in Boston. I do not want them to be given in detail because then we go the other way, but I feel that a good solution of that would be as follows:

Matters described under category 2, which are the resolutions, shall first be called by number. Each resolution has been assigned a definite number, depending on the order in which your Secretary's Office received the resolutions. As you get up to give the resolution, please state, "This is No. so-and-so." It will be called by number so that there will not be any trouble. When you get up, in addition to the number, give the name of the delegate presenting the resolution and for whom he is presenting it. There is a title to the resolution. Please read the title of the resolution. Then I am going to ask you to do the thing which my good friend, Jim Reuling, insisted upon, and I agree with him; read the "Resolved" portions of your resolution, leaving out the "Whereases." The "Whereases" are arguments in favor of and should be before the reference committee for your argument and will be taken up there. If we hold to this plan, we shall save a great deal of time, and yet we shall get adequate understanding of the resolution in my opinion. Then the Chair will assign it to the proper reference Committee.

In your folders you will find resolutions, supplementary reports and listings of them by letters and numbers showing the name of the reference committee to which they are referred, including the chairman of the committee, so if you miss what the chairman says, just get your packet out and read where it was assigned. We have tried in all ways to help you to be perfectly clear at all times as to where everything before the House is.

I want to congratulate this House at this time. I have had marvelous cooperation in connection with resolutions. Ordinarily, on the morning of a meeting the Speaker goes into the Secretary's office and finds 50 or 55 resolutions waiting for him, and to assign them to the proper committee without knowing what they are is a job for your Speaker and Vice Speaker. This morning I went in and Miss McGovern said, "We have only one more so far." You may have some out there waiting for me, you may fool me, but we have most of them in our hands, I am sure. I appreciate that, and ask for your continued help.

Further, I want to call attention to the fact that this is not the only day on which resolutions may be introduced. They may be introduced willy-nilly on Wednesday. On Thursday, however, they may be introduced if they come from the sections or are an emergency, or if they are presented by unanimous consent, so we may have more resolutions. If we get late resolutions, they obviously cannot be put in your hands mimeographed. If you remember, last time we had a little trouble because everybody went around the table and reached over and pushed them and shuffled them like a deck of cards, and nobody got what he reached for. So I have got this table over here, and, if you noticed, there is a rope up there, and I am going to have the Master Sergeant and his fellows standing there, and they are only going to let you go through in one line. The resolutions will be placed numerically, and as you go by pick them up numerically and don't reach over because if you do the Sergeant-at-Arms is going to flash his badge on you.

All business adopted by the House is transmitted by the Secretary and General Manager to its proper destination. The Board of Trustees, however, is obligated by the laws of the State of Illinois, under which the American Medical Association is incorporated, to decide whether any action is legally correct and if the financial requirements are wise. The Board must control all action. At times legal counsel advises the Board that portions of resolutions if carried out would result in legal penalties and the Board of Trustees must therefore estop all action. Some part of the resolution may be legal, however, and by direction the Board must carry that part out even though the main object of the resolution is impossible of accomplishment. Each reference committee should therefore study every item before it very carefully and request our Law Department to give advice where indicated before reporting on the matter to the House.

Reference committee reports will be called for in order as deemed most appropriate by the Speaker. We shall appreciate notification at once as soon as the chairman has his report ready.

In election voting the Secretary will read the names of delegates in order as listed by states for the roll call. The Chairman of Tellers will verify each name as the ballot is cast. In other voting by division count or ballot, the Tellers will determine the vote and report the result to the Speaker.

Your Speaker wishes to compliment this House on its usual astuteness and efficiency. We fear that soon you will attain such perfection that we shall have no more room for innovations of procedure. However, that reminds me of a quotation whose author I do not know. I often repeat it to myself when I feel a little self-satisfied: "For never yet hath any man attained to such perfection but that time or use hath brought addition to his knowledge, or made correction or admonished him that he was ignorant of much that he had thought he knew."

REPORT OF REFERENCE COMMITTEE ON REPORTS OF OFFICERS

Dr. William L. Estes Jr., Chairman, Pennsylvania, presented the following report, which was *adopted:*

Address of the Speaker.—Vincent Askey is a magnificent presiding officer of the House. His thoughtful and thorough concentration on the improvement of our knowledge and familiarity with parliamentary procedure, and the mobilization of every feature to facilitate the business of the House to lose as little time as possible in routine so that the concentration of our members can be upon intelligent consideration of the business at hand, deserves the plaudits of his confreres. The introduction and identification of new members is a splendid innovation. A leniency and some latitude in the interpretation of rules is always wise, unless, as he has stated, the rights of others are thereby jeopardized. Explanation of a motion to reconsider, and that it can be made only by one who voted on the prevailing side, is timely; likewise that a motion is never carried until an announcement of the vote by the Chair and its relation to the question of further discussion has been properly clarified. Other often misused or misunderstood parliamentary procedures, such as the motion to rescind and an appeal from the decision of the Chair, have been accurately outlined.

The introduction of dividers and separate compartments in the folders of every member for the material for each reference committee should make for better filing of our documents and for easy access to them. If these compartments were removable from the folder, there would be an added convenience. The detailed outline of the method of handling previously considered items and the spelling out of the method to be pursued in the introduction of resolutions will and has already improved the despatch with which this routine can be carried out.

Most timely is the reminder that the Board of Trustees, in compliance with Article VIII of the Constitution, is obligated by the laws of the State of Illinois, under which we hold our charter, to decide as to the legality of all action taken by the House. Your committee has been advised that members of the Association's Law Department are available to consult with each reference committee of the House. Therefore we would particularly reemphasize the Speaker's admonition that "each reference committee should study every item before it very carefully, and request our Law Department to give advice where indicated before reporting on the matter to the House."

Astuteness and efficiency, to which the Speaker refers, certainly rest likewise on his broad shoulders, and from that source, in many respects, have been contagious to members of the House. He deserves our grateful thanks for his outstanding contributions to better and more expeditious procedure by this deliberative body.

Introduction of New Delegates

The Speaker introduced 19 new members of the House of Delegates with the following remarks:

I have in my hand the last available list of the new members, and I wish as I call their names that they would stand up because I feel that these new members should be made welcome. I think some of us remember when we were neophytes in this House and did not know many men and it was a little bit difficult to orient ourselves. I am sure that if we put the old right hand out and make them feel at home and introduce ourselves to them, they will be very happy. After I read this list, if there are other new members sitting in the House for the first time, if they will please announce their names to me, I shall introduce them and be happy to do so.

The new delegates are: Drs. Cyril J. Attwood, California; Edward E. H. Munro, Colorado; Gordon B. Wilder, Indiana; W. Vinson Pierce, Kentucky; Robert van Lieu Campbell, Maryland; Henry F. Howe and Nicholas S. Scarcello, Massachusetts; Earl F. Leininger, Nebraska; Coy S. Stone, New Mexico; James Greenough and Dan Mellen, New York; Elias S. Faison, North Carolina; Wilkie D. Hoover, Oklahoma; C. Henry Bloom, Pennsylvania; Troy A. Shafer and Leopold H. Reeves, Texas; W. Linwood Ball, Virginia; Charles L. Leedham, Section on Military Medicine; Francis M. Forster, Section on Nervous and Mental Diseases.

In Memoriam

The Speaker presented the following list of members of the House of Delegates and/or officers of the American Medical Association notice of whose death had been received since the 1955 annual meeting. The dates following the names indicate the years of service in the House or as officers of the Association.

Abt, Isaac A., Chicago, Section on Diseases of Children (Pediatrics) 1919-1935; Received Distinguished Service Award, 1948.
Bartlett, Charles J., Connecticut, 1925.
Chase, Peter Pineo, Rhode Island, 1948.
Colt, James D. Sr., Kansas, 1933-1935.
Crouch, John B., Colorado, 1935.
Cunniffe, Edward R., New York, 1929; 1932-1936; 1938-1944; Member, Judicial Council, 1936-1954; Chairman, Judicial Council, 1944-1954.

Curtis, Arthur H., Chicago, Section on Obstetrics, Gynecology, and Abdominal Surgery, 1932-1934.
Frothingham, George E., Michigan, 1923-1926.
Hayes, Robert H., Illinois, 1941-1951.
Hess, Julius H., Chicago, Section on Pediatrics, 1951.
Hunt, Preston, Texas, 1938, 1940.
Koch, Otto W., Missouri, 1929.
Kurth, Harold R., Massachusetts, 1951, 1954-1955.
Luce, Henry A., Michigan, 1924, 1931-1946.
McGoldrick, Thomas A., New York, 1936-1953, *Vice President,* 1947-1948; Member, Council on Medical Service, 1944-1952.
Merritt, Edward L., Massachusetts, 1938, 1939
Moncure, Philip St. L., Virginia, 1935.
Newton, George A., New York, 1938
Pettit, Joseph A., Oregon, 1918, 1920-1925, Member, Board of Trustees, 1925-1935.
Porter, John M., Kansas, 1948-1953.
Pratt, Joseph H., Boston, Section on Practice of Medicine, 1914.
Randel, Henry A., California, 1953.
Reese, George W., Pennsylvania, 1926, 1930
Ross, William H., New York, 1932-1935, 1941.
Scott, Arthur C. Jr., Texas, 1949-1955, Member, Council on Medical Service, 1955-1956.
Shanklin, Eldridge M., Indiana, 1927-1928.
Simpson, Leo F., New York, 1950-1951.
Skipp, William M., Ohio, 1938, 1942-1955
Stevenson, James, Oklahoma, 1944-1954, Member, Council on Constitution and Bylaws, 1951-1955.
Stewart, James L., South Dakota, 1902
Taylor, H. Marshall, Florida, 1923-1924, 1926, 1933.
Thompson, Sam E., Texas, 1934-1936, 1938-1939, 1941-1943
Van Duzen, Rex E., Texas, 1949.
Watkins, W. Warner, Arizona, 1924.
Whitacre, Rolland J., Cleveland, Section on Anesthesiology, 1955.
Whitehill, James L., Pennsylvania, 1948-1955.

The House rose in silent tribute to the memory of its deceased members.

Presentation of Distinguished Guests

The following distinguished guests were introduced by the Speaker:

Dr. Lon W. Morrey, Editor, Journal of the American Dental Association.

Dr. E. H. Volwiler, President, American Drug Manufacturers' Association.

Mr. Ray E. Brown, President, American Hospital Association.

Miss Frances L. A. Powell, Secretary, American Nurses Association.

Dr. Ronald Robertson, Vice President, American Pharmaceutical Association

Dr. Robert K. Cutter, *President, American Pharmaceutical Manufacturers'* Association.

Mr. August Pritzlaff, Past President, American Association for Health, Physical Education, and Recreation

Mrs. Alice F. Sturgis, Parliamentarian, American Bar Association.

Sir Alexander Murphy, *Past President,* Queensland Branch, British Medical Association.

Dr. Tomio Ogata, University of Tokyo, Japan.

Dr. Moshe Sherman, President, Israel Medical Association.

Remarks of President of Woman's Auxiliary, Mrs. Mason G. Lawson

Mrs. Mason G. Lawson, President of the Woman's Auxiliary to the American Medical Association, was introduced by the Speaker and addressed the House as follows:

Mr. Speaker, Members of the House of Delegates, and Distinguished Guests: Again it is my pleasure to bring you up to *date on the activities* your Woman's Auxiliary and to extend to you the greetings of our now 73,639 members with their best wishes and the pledge of *continued cooperation in any project* or program which you deem suitable for Auxiliary participation.

The *figures* contained in *this* report must *of necessity* be incomplete because our fiscal year runs from July 1 to June 30 and some of our reports cannot be completed until that date.

No other woman's organization has a stronger or more unifying bond than does the Women's Auxiliary, first because of our membership restrictions which require that we be wives of doctors of medicine who hold membership in their respective county and state *medical societies* and in the American Medical Association. We do have a few members in some states and territories who *hold a close relationship to a* physician, such as mothers or sisters of unmarried physicians. We also have a category of associate membership for those wives whose husbands are members in good standing of their county and state medical associations but who are not members of the American Medical *Association.* I am happy to report to *you* that this number is rapidly decreasing, because we feel that we have brought a little pressure on the wives, and they wish to hold active membership in our Auxiliary rather than associate membership

Secondly, because of our close relationship to the medical profession we have a common purpose. We have never deviated from our original concept of the function of a group such as ours, which is defined as follows in our constitution· "To assist the American Medical Association in its program for the advancement of medicine and public health." Fortunately unity does carry with it uniformity. There are such a variety of programs and projects in which our states and counties are currently engaged that it would be impossible in the short time to mention them all. However, knowing that you share my pride in the accomplishments of our organization, I hope you will permit me the liberty of a little dignified boasting.

All but one of our state auxiliaries have participated in financial assistance to our medical schools through contributions to the *American Medical Education Foundation. This year* we changed our fiscal policy and therefore had no carryover from the previous *year's contributions.* We are proud to report that our AMEF contribution to date, and remember we still have until June 30, is $83,234.46. This does not include the 10% of our current budget, $6,502.50, which the Board of *Directors* will recommend to the House of Delegates as our AMEF contribution for the year. This will bring our total to $89,736.96. Together with the $15,699.18 credited to the Auxiliary in the 80 Dimes Campaign our over-all total for 1955-56 will be $105,406 14. *We are very* proud to report to you that since 1951 our Auxiliary has contributed $305,590.16 *to the American Medical* Education Foundation. Our Board of Directors will also recommend to our House *of Delegates $100 to continue our* membership in the World Medical Association, $100 to the Crusade for Freedom, $100 to the Student A. M. A. Foundation for loans to students, and $100 for the Committee on Careers in Nursing.

Second in popularity among our projects was the sale of *Today's Health* subscriptions. Our subscriptions increased to 57,711 over last year's total of 53,214. Recruitment of Nurses and Other Medical Personnel ranked first in the number of counties participating, but ranked *third in the number of* state projects You *may* be *interested to know* that this *year,* auxiliaries throughout the country made available for nursing education $148,331.52. The total amount for loans to student nurses was $42,475.77. The total amount for scholarships for student nurses was *$100,876.75.* The total for postgraduate *study* was $3,050 The total for practical nurses was $1,009.29.

All states have been active in medical legislation and we are confident that our efforts in this field have been recognized b our legislators.

Ninety-three per cent of our states report programs in safety rural health and community health studies, 85% were active in civil defense programs. Forty states are promoting some type of mental health program. Under a variety of projects many of our *states* have *programs* relating to better child health and better care of our aging population.

Progress has been made in three new projects Eighty four counties have made surveys of the contributions made by physicians in time and money to charity and *community* affairs Forty-six counties have participated in science fairs, and the Auxiliary is providing chaperones for the two young ladies from California and Oklahoma who are attending this convention as national winners. Thirty states have completed a "*Who's Who*" in the medical auxiliary, listing each member's activities and membership in lay organizations.

Including the 34 constituent auxiliaries which *I* visited this year, I have attended 77 meetings of various American Medical *Association* departments and national organizations Sixteen additional state meetings were covered by other officers *and* chairmen, and 16 additional national and regional meetings were covered by this group. Throughout my *travels I* have been impressed with a much closer affiliation between the state medical associations and their auxiliaries and the *increasing* trend in directing our activities in useful channels. We appreciate your encouragement and we hope that we shall always merit your confidence.

I must express my grateful thanks to Dr. Ernest B Howard, who as our liaison *officer* between the Auxiliary *and our* Advisory Committee, has given us invaluable service. My thanks *also to* Dr. Lull and all of the American Medical Association personnel, and most *especially to* our Advisory Committee headed by Dr Blasingame. All of them and all of *you* have assisted *us in* our program of service to the *medical* profession and to our individual communities. It has been a great pleasure this year to have served you through the Auxiliary. I appreciate so much the many courtesies which you, and the House of Delegates, have extended to me and which you, individually, have extended to me when I have visited your states. Thank you very much.

Message from President Eisenhower

Dr. Elmer Hess, President of the American Medical Association, informed the House that he had talked with General Snyder, the President's physician, earlier in the morning (Monday, June 11) and that General Snyder had told him that the President of the United States sends his best greetings to this House of Delegates with gratitude for the services rendered to his Administration and was very hopeful that we would have a very, very wonderful meeting; his blood pressure was normal, his temperature was 99, his pulse was in the high 70's, and he had been sitting in his chair for a few minutes

Address of the President, Dr. Elmer Hess

Dr. Elmer Hess, President, delivered his address, which was referred to the Reference Committee on Reports of Officers. (See Dr. Hess' address in THE JOURNAL, June 23, 1956, pages 734-738.)

REPORT OF REFERENCE COMMITTEE ON REPORTS OF OFFICERS

Dr. William L. Estes Jr., Chairman, Pennsylvania, read the following report, which was adopted

Address of the President.—In the discussion of his address with Dr. Hess by your committee, the topics to which he referred were taken up in order. We believe he is sound in stating that there should be not only loyalty by each physician to his medical school but also loyalty to medical education as a whole, and that support of medical education by the practicing physician is a must in spite of any existing local conflicts, if we are going to stimulate industry to contribute annually large sums for this purpose and if we wish to keep government out of the operation of medical schools. Dr. Hess calls attention to serious differences of opinion between the educators in our medical schools and the privately practicing medical profession, largely the result of misunderstanding, and suggests that most of these differences should be ironed out at the local level around the conference table, and that medical teachers should be active members of county and state as well as national organizations Your committee believes that this is a tremendously important and pressing problem, and that it can only be solved satisfactorily at the local level. We would recommend that, through appropriate channels, this matter be referred to the constituent state medical societies, and likewise through the membership of this House reporting back to the various state medical societies. This would be for implementation when and where it would seem necessary by way of the local county medical societies.

Dr. Hess deplores the many controversies leading to litigation in the realm of hospital-physician relationships and believes those, likewise, can best be resolved by local level conferences of the organization implicated. He suggests that careful study of two reports recently submitted to the House, the report of the Committee to Review the Functions of the Joint Commission on Accreditation of Hospitals and the report on Private Practice Medical School Faculty Members, will be helpful in reaching bases for agreement.

It is gratifying to learn that through conferences with various governmental agencies we have been able to broaden our contributions to the solution of many national health problems.

Dr. Hess' report on our relations with the American Legion is of great interest, particularly to know that problems of mutual interest are still under consideration by the Committee on Federal Medical Services of the Council on Medical Service.

Your reference committee certainly agrees in the importance of participation by the American Medical Association in the prevention of the great holocaust that results from the appalling increase in casualties from traffic accidents. We would likewise recommend attendance by all interested members of the House at the panel discussion on medical aspects of crash injuries to be held at 9 a. m. Friday, June 15, 1956, in Room A on Navy Pier.

Dr. Hess' concern for the problem of the aging is shared by most of us, and we agree that the most important problem—how to keep these people healthy, happy and occupied—has not yet been satisfactorily solved. Your committee would recommend that part of Dr. Hess' report concerning problems of the aging be referred for implementation to the Committee on Aging of the Council on Medical Service.

Your committee is also impressed by the importance of the national survey on mental health now being conducted with the cooperation of our Council on Mental Health, the American Psychiatric Association, and many other groups, and would concur with Dr. Hess' recommendation that it should receive every assistance and implementation possible at the local level. Also, we concur in his recommendation that prepaid voluntary health insurance, because of its wide acceptance by the public, should receive unremitting exploration for potential new fields for coverage on a sound actuarial basis.

In connection with Dr. Hess' reference to Social Security and the question of compulsory or voluntary inclusion of physicians, your committee believes it would be well to point out that the American Medical Association has been concerned with two phases of the problem—(1) the constant expansion of the Social Security program, and (2) the inclusion of physicians—and that in Dr. Blasingame's supplementary report from the Board of Trustees, presented to the House on Monday, the position of the Association concerning Social Security problems has been very ably presented.

The activities of the Law Department are well pinpointed by Dr. Hess, and we would suggest that these should be better publicized. One of the important developments of the sectional meetings of the medical profession with members of the American Bar Association has been the development of codes for action between state medical societies and local bar associations. The importance of conferences such as these can be better realized when it is understood that 60% of the cases in ligitation countrywide have some medical implication. Your committee would recommend that the program of sectional meetings between the medical profession and the American Bar Association should be expanded, and that consideration be given likewise to the expansion of the Law Department as indicated.

The tremendous field of effort that the Council on Medical Service represents, the need for better attendance at county meetings, and more complete perusal of THE JOURNAL are other important comments from our President. Payment of dues for membership in the American Medical Association is a matter of great concern. Your committee is informed that the question of dues is under study by the Board of Trustees at present. Dr. Hess' reference to this problem certainly points up important elements for consideration

Dr Hess' description of the present status of physicians' relations to the labor movement and the position of certain labor leaders concerning health insurance has far-reaching implications We must be on sound ground in our negotiations concerning mutual problems. Your committee concurs in Dr. Hess' belief that as long as we can continue to produce good medical care at reasonable cost and as long as we respect the workers' rights in their own fields of organization, we shall continue to have friends in the ranks of labor.

We can all approve Dr. Hess' admonition concerning participation as individuals in our rights as citizens and exerting our rights of franchise.

Elmer Hess has proved a superlatively magnificent ambassador for American medicine. His keen perception, his intuitive sense of impending problems, his quick reaction to change a planned program of procedure according to the situation that develops or exists, his direct and forthright approach, his integrity, and an abiding sense of humor have carried him and the organization he has so well represented into a higher echelon of security and understanding. His declaration and interpretation of the basic principles on which American medicine is founded and has its being have widened the horizons of appreciation and friendship for those who toil for the sick and have strengthened his confreres in their efforts to eliminate the ills of the medical body politic. Elmer Hess has earned the admiration, thanks, and plaudits of his constituents.

Address of the President-Elect, Dr. Dwight H. Murray

Dr. Dwight H. Murray, President-Elect, delivered an address, which was referred to the Reference Committee on Reports of Officers. (See Dr. Murray's address in THE JOURNAL, June 23, 1956, pages 738-740.)

REPORT OF REFERENCE COMMITTEE ON REPORTS OF OFFICERS

Dr William L. Estes Jr., Chairman, Pennsylvania, presented the following report, which was adopted:

Address of the President-Elect.—In his opening paragraphs Dr. Murray states that he believes the greatness of the American Medical Association depends upon its long and outstanding service in the public interest, its tireless efforts to promote the art and science of medicine, and its constant adherence to the principles of freedom and individual enterprise. This is indeed indicative of his broad approach to the task that lies ahead.

His reference to the opportunities for the general practitioner in hospitals is timely and can be taken to heart. His statement that general practitioners desire only the right to make available to their patients all of the modern advances of medical science, *without discriminatory* restrictions unrelated to professional attainment, comes with the voice of authority from one who has so splendidly represented that group in high places. His warning against a growing tension between general practice and specialization should be a matter of concern to us all. Your committee would echo his admonition that, instead of factional differences, we should be thinking rather in terms of the medical profession as a whole and of our responsibility to the American people to provide ever better care for our patients.

In reviewing the results of the public opinion survey of the medical profession and of the American Medical Association, Dr. Murray particularly points out that the public tends to be critical of us for high fees, for coldness and impatience, for lack of frankness, and for unavailabilty, and that these findings should not be ignored. Steps should be taken to eliminate these criticisms, and the job is one for the individual physician. Another criticism is excessive time spent by patients waiting in our offices to see us. The survey shows that patients are complaining twice as much about long waiting as about fees. Brief concentration on this problem and the introduction of a few efficiency measures should eliminate in large part this habit-forming practice.

Your committee would commend the wisdom of frank explanation to the patient of his illness, so that he has a clear concept of its nature and its course as stressed by Dr. Murray. The patient comes to us because he is concerned about his physical condition. Honesty and frankness in explaining the diagnosis and treatment required will dispel a great deal of anxiety and inspire confidence. While there properly are exceptions to this proposal as an invariable practice, a greater tendency to take time to explain will pay splendid dividends in better public relations. Dr. Murray also highlights his concern for the better care of the aging and the aged to insure good health in old age and the relief of the physical pains and disabilities of the aged.

Dr. Murray concludes by predicting revolutionary changes in the practice of medicine in the years ahead, and indicates the responsibility of the medical profession to exert its influence to the end that any changes would be to the best interests of the public and that voluntary health insurance programs should play a beneficial role by successfully competing with the more pernicious closed panel practices coordinated with third party financing. He further stresses the importance of evaluating accurately the plan proposed by the cooperating committee on graduates of foreign medical schools, of which the American Medical Association is a parent member, designed to test and evaluate foreign-trained physicians, which has been presented to the House.

It is not difficult to foresee a splendid year of accomplishment ahead for one who has had so magnificent a background of service and record of achievement and understanding of organizational problems as Dwight Murray, and as he takes up his task as President of the Association, he can be assured of the full cooperation of his many friends and constituents.

Report of the Board of Trustees

The Speaker referred items in the report of the Board of Trustees as printed in the Handbook of the House of Delegates (see THE JOURNAL, May 12, 1956, pages 156-159) to reference committees as indicated:

Financial Statement, Council on Medical Physics, Committee on Rehabilitation, American Surgical Materials Association, Annual and Clinical Meetings, Closing of the Print Shop, Report of the Auditor, and Report of the Treasurer were referred to the Reference Committee on Reports of Board of Trustees and Secretary.

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Dr. Woodruff L. Crawford, Chairman, Section on Pediatrics, read the following report, which was adopted:

Financial Statement.—Your reference committee reviewed the Financial Statement of the Board of Trustees. Certain of the Trustees appeared before the committee for purposes of information and clarification. We note with satisfaction the increased revenues from both subscriptions and advertising in THE JOURNAL and other magazines. While there was also an increase in costs, these have more than been offset by the revenues obtained. The increase in advertising revenues for *Today's Health* is understandably less than from the other journals and its publication is a slight drain on the Association's resources. However, as a public relations vehicle we believe it is serving a very useful purpose.

Council on Medical Physics.—Your reference committee approves the action of the Board of Trustees on the formation of a Council on Medical Physics replacing the former Council on Physical Medicine and Rehabilitation.

Committee on Rehabilitation.—Your reference committee concurs with the recommendation of the Board of Trustees. This refers to the establishment of a Committee on Rehabilitation as requested by the action of the 1955 interim session of the House of Delegates in Boston. The Board of Trustees amended the report to read: "*It is believed that rehabilitation problems should be assigned to an intra-Association liaison group with representation from all interested American Medical Association councils, sections, and committees dealing with the subject.*"

Your committee supports the recommendation of the Board that this House of Delegates rescind the previous action for the reasons stated by the Board of Trustees, and recommends that the Board of Trustees be given authority to set up this committee as outlined in that portion of their report, without including representatives from each of the scientific sections.

American Surgical Materials Association.—Your reference committee approves the action of the Board of Trustees in sponsoring the establishment of the American Surgical Materials Association.

Annual and Clinical Meetings.—Your reference committee notes that the House of Delegates and Board of Trustees have approved the places and dates for the annual meetings from 1957 through 1960 and for the clinical meetings in 1956, 1957, and 1958.

Closing of the Print Shop.—Your reference committee studied in great detail that portion of the report of the Board of Trustees regarding the closing of the print shop. The decision reached by the Board to close the print shop at the headquarters building and to contract for the printing work with an outside firm was activated by the Headquarters Survey Report (the so-called English report), approved by the House of Delegates at the Atlantic City meeting in 1955.

There appeared before your committee for purposes of information and clarification the Chairman of the Board of Trustees, other members of the Board, the Secretary and General Manager, and the Editor of THE JOURNAL. Mr. L. E. O'Neill, President of the Chicago Typographical Union No 16, who wrote a letter to each delegate about this matter, also appeared before the committee at our invitation. He expressed the hope that if present arrangements are not satisfactory the Union may be permitted to confer with the Board of Trustees in an attempt to have the material again printed in the Chicago area.

Your reference committee agrees with the action of the Board of Trustees in its decision, following the instructions of the House of Delegates, and recommends approval of this portion of the report.

The Auditor's and Treasurer's Reports.—Your reference committee reviewed the Auditor's and Treasurer's Reports. It is satisfied after consultation with members of the Finance Committee of the Board of Trustees that the changes in investment policy, based on the best advice obtainable, are in the best interests of the Association and approves their efforts in the conservation of the Association's resources.

Military Status for the Public Health Service and Voice of America and Radio Free Europe were referred to the Reference Committee on Legislation and Public Relations.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. Willis H. Huron, Chairman, Michigan, presented the following report, which was adopted:

Military Status.—Your committee wishes to state that S. 2587 has been passed and is now a public law. This gives the President authority to order military status for the Public Health Service commissioned corps in time of national emergencies, and was the intent of Resolution No. 1 which was referred to the Board of Trustees by the House of Delegates in June, 1955.

Voice of America and Radio Free Europe.—Your reference committee wishes to thank the Board of Trustees for the information contained in its report.

Chamber of Councillors to the Reference Committee on Miscellaneous Business.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Joseph C. Griffith, Chairman, Wisconsin, submitted the following report, which was adopted:

Establishment of Chamber of Councillors.—This was requested by a resolution passed by the House of Delegates at its meeting in Boston. The Board of Trustees has the power to seek advice from qualified persons outside the medical profession on an *ad hoc* basis. Your reference committee approves the action of the Board of Trustees that this resolution be not adopted.

Improvement of the Care of the Patient to the Reference Committee on Hygiene, Public Health, and Industrial Health:

REPORT OF REFERENCE COMMITTEE ON HYGIENE, PUBLIC HEALTH, AND INDUSTRIAL HEALTH

Dr. Martyn A. Vickers, Chairman, Maine, read the following report, which was adopted:

Improvement of the Care of the Patient.—At its Boston Meeting the House of Delegates approved a supplementary report of the Board of Trustees recommending that physicians of the United States do everything possible to improve patient care and accept responsibility for providing necessary leadership for establishment of Joint Committees for the Improvement of the Care of the Patient at state and local levels; however, the House requested definition and clarification of what groups would constitute the Joint Committees. This portion of the present report of the Board of Trustees defines and clarifies the composition of state and local committees for the Joint Commission for the Improvement of the Care of the Patient, and thus adoption is recommended.

Scientific Sections and Membership of Council on Medical Service to the Reference Committee on Amendments to the Constitution and Bylaws.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO THE CONSTITUTION AND BYLAWS

Dr. Jay J. Crane, Chairman, Section on Urology, presented the following report, which was adopted:

Scientific Sections.—Your committee has considered the portion of the report of the Board of Trustees under the title of Scientific Sections. It was noted that the Board of Trustees requested a review of the pertinent sections of the Constitution and Bylaws of the Association dealing with the scientific sections and concluded: "In summary it seems clear from the provisions of both the Constitution and the Bylaws that the purpose of the Scientific Assembly is to provide a forum for a discussion of the scientific aspects of medical practice. All other aspects, social [sociological], political, economic, etc., are within the purview of the House of Delegates." With this summary your committee agrees, and by so agreeing admonishes the scientific sections that anything on their programs other than scientific material would seem to have no place in their deliberations.

Membership of Council on Medical Service.—This reference committee also had referred to it that portion of the report of the Board of Trustees relating to the membership of the Council on Medical Service. The Council on Medical Service last March recommended to the Board of Trustees that the membership on the Council be increased to nine members and asked that consideration be given to the advisability of eliminating provision for ex officio members. The Board of Trustees concurred in the recommendation of the Council and transmitted it to the House for consideration and appropriate action. After due consideration, your reference committee believes that the work of the Council would be facilitated if the ex officio members were eliminated, except for the immediate Past President, and three elected members added for them. This will give the Council nine members elected by this House, rather than six as presently constituted. It therefore recommends that:

(1) The first sentence of Chapter XI, Section 2, (C) of the Bylaws be amended to read as follows: "The Council on Medical Service shall include nine Active or Service Members."

(2) The second sentence of Chapter XI, Section 2, (C) of the Bylaws be amended to read as follows: "All members shall be elected by the House of Delegates for terms of five years so arranged that at four annual sessions the terms of two members expire and at one annual session the term of one member expires."

(3) The last sentence of Chapter XI, Section 2, (C) of the Bylaws be eliminated, so that the new Chapter XI, Section 2, (C) of the Bylaws will read: "The Council on Medical Service shall include nine Active or Service Members. All members shall be elected by the House of Delegates for terms of five years so arranged that at four annual sessions the terms of two members expire and at one annual session the term of one member expires."

SUPPLEMENTARY REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO THE CONSTITUTION AND BYLAWS

Dr. Jay J. Crane, Chairman, Section on Urology, read the following supplementary report, which was adopted:

Your reference committee has given further consideration to that portion of the report of the Board of Trustees relating to the membership of the Council on Medical Service. In order to comply with the expiration dates for terms of office of members of the Council as specified in the amendment to Chapter XI, Section 2 (C) adopted yesterday (June 13, 1956) by the House of Delegates, it will be necessary that the initial terms of office of two of the three new members of the Council be for periods of less than five years. Your Reference Committee therefore recommends that:

Chapter XI, Section 2 (C) of the Bylaws be further amended by adding the following sentence: "The initial terms of the three new members of the Council arising out of the increase herein provided for shall be for periods as proposed by the Board of Trustees."

Foreign Medical Graduates and Accreditation of Hospitals to the Reference Committee on Medical Education and Hospitals:

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. George S. Klump, Chairman, Pennsylvania, stated that the portion of the report of the Board of Trustees concerning foreign medical graduates would be considered by the reference committee with the report of the Council on Medical Education and Hospitals.

Dr. Klump submitted the following report, which required no action:

Accreditation of Hospitals.—This paragraph announces the selection of Dr. Raymond F. Peterson, Butte, Mont., a member of the House of Delegates, to fill the unexpired term of Dr. Rolland Whitacre as one of the representatives of the American Medical Association on the Joint Commission on Accreditation of Hospitals and requires no action.

Supplementary Reports of the Board of Trustees A to J

Supplementary reports of the Board of Trustees were presented to the House by the Chairman and members of the Board as follows: Supplementary report A by Dr. Gunnar Gundersen, Chairman, and Dr. F. J. L. Blasingame who presented an additional statement on social security; B by Dr. Leonard W. Larson; C by Dr. David B. Allman; and the remainder by Dr. Gundersen. The reports were referred by the Speaker to reference committees as indicated at the beginning of each report.

A. OASI Polls

Supplementary report A was referred to the Reference Committee on Legislation and Public Relations.

The House of Delegates, at the Boston meeting, recommended to state societies (Resolution No. 16) that they poll their entire memberships on the question of inclusion of physicians under the Old Age and Survivors Insurance provision of the Social Security Act, and that the results of these polls by the state societies be transmitted to the Board of Trustees. The Board wishes to report the following results from the polls that have been taken:

Although the questions asked and other features of the polls varied considerably, *it can be concluded that the polls taken by* 34 state associations and two territorial associations indicate opposition to compulsory coverage of physicians under Old Age and Survivors Insurance; of these 34 polls, 23 indicate some support of voluntary coverage, and 1 indicates a neutral position on such coverage. Nine state associations will take no poll; three of these sent reports of actions by their councils opposing compulsory coverage and not opposing voluntary coverage, and a fourth state furnished part of its results of a 1954 poll which could not be interpreted for the present purposes. Three state association polls are still in process (May 31). Finally, only three polls could be interpreted as *favoring compulsory coverage*, and only one of the three was conclusive.

In connection with this subject attention is called to an article by Dr. F. J. L. Blasingame entitled "The History of Social Security," which appeared in the Nov. 19, 1955, issue of The Journal.

Social Security

Perhaps the most important single issue confronting the public and medicine today is the proposal to amend the Social Security Act now being debated in the United States Senate. The fate of medical care in this country is literally hanging in the balance. The legislative outcome may well have serious consequences for our profession. The status of this legislation has been reviewed in the progress report of the Committee on Legislation, and the Chairman of that committee will make some additional comments. It is my purpose to distinguish clearly between two proposals of medical interest relating to the Social Security System with which we have been concerned and to emphasize the profound difference between them in their effect on medical practice.

The proposed amendment to the Social Security Act embodied in H.R. 7225, which would establish a cash benefit under the Old Age and Survivors Insurance System for disabled beneficiaries beginning at age 50, constitutes a serious threat to American medicine. It is obviously one important step on the road to a system of complete federal medical care. No government can long provide cash benefits as a right under a so-called social insurance system without eventually injecting itself into the physician-patient relationship. It will necessarily become a responsibility of government to regulate the medical care and the rehabilitative programs that are associated with the payment of the cash benefits. Because of this undesirable impact on medicine, the incalculable cost to the public, the inhibiting effect on the patients' will to be rehabilitated, and for other reasons which have been detailed in many communications to you from our Washington Office and the Committee on Legislation, we have properly opposed this proposal and recommended that a careful nonpartisan study be made of disability as it relates to employability for the purpose of determining the best possible methods of conducting constructive programs in this area.

The *second* proposal to which this House has addressed itself on several occasions is Social Security coverage of physicians. We have repeatedly expressed our opposition to compulsory coverage but have indicated that we would not oppose voluntary inclusion. We have endorsed as an alternative the Keogh-Jenkins bills *providing for the* setting aside of a limited amount of current income into a fund with the privilege of deferred taxation and withdrawal, at the then taxable levels, of those contributions at the age of 65. It is imperative that we distinguish clearly between this problem of coverage of physicians and the far more dangerous disability proposal. The fact should be recognized that the shape of medical practice in the future is not directly related to the inclusion or exclusion of physicians under OASI. It is a matter of vital importance to us as individuals, but it cannot, per se, stimulate further government intrusion into medical care. On the other hand, the disability amendment obviously brings the Social Security Administration closer to the regulation of medical care than ever before. It is highly important that the medical profession understand this distinction and understand it clearly so that the impact of these two fundamentally different proposals may be placed in their proper perspective. Public understanding of the potential implications of disability coverage under OASI is urgently necessary so that a political atmosphere can be created that will stifle rather than nurture such growth. We have powerful friends in this effort whose full force and effective cooperation we must sustain.

H.R. 7225 contains no provision for compulsory coverage of physicians, so therefore it is not an issue in Congress at this time. Furthermore, the polls that have been taken indicate clearly that the vast majority of our members support the stand that you have taken against compulsory coverage. The disability amendment may or may not be adopted by the Senate this very week. If it is defeated and its defeat is sustained by the Conference Committee in the House of Representatives, we shall have been given a moratorium, but only a moratorium, of perhaps two years in which to prepare for the next onslaught. Let us devote our energies and our most mature judgment to this fundamental question so that we may counter similar proposals in the future with evidence so incontravertible and alternative measures so obviously effective and consistent with the structure of our Republic that the defeat of such measures will be inevitable. Finally, there should be no feeling of defeatism. If we can stem this tide now, we can win a lasting victory provided we appreciate fully the significance of these disability proposals and sustain our present active interest.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. Willis H. Huron, Chairman, Michigan, submitted the following report, which was adopted:

Supplementary Report of Board of Trustees A on O. A. S. I. Polls, presented by Dr. Gundersen, Chairman of the Board of Trustees.—Your committee is of the opinion that the polls, as they have been conducted, are of questionable value, primarily because of the number of variables present in the questionnaire as sent out by the various state and county societies. Your committee believes that if a poll of this magnitude is to have any significance, the questionnaire should be composed by those individuals of the American Medical Association who are familiar with the Social Security Act in its entirety and then be made available to state or county medical societies.

Supplementary Report of Board of Trustees A on Social Security, presented by Dr. F. J. L. Blasingame, Trustee.—This report is of such an excellent nature that any comment would be superfluous. Your committee wishes to commend the Board of Trustees and Dr. Blasingame on this report and recommends that each member of the House of Delegates call it to the attention of his constituent society, and that the Board of Trustees have it published in an early issue of The Journal.

B. Commission on Medical Care Plans

Supplementary report B was referred to the Reference Committee on Insurance and Medical Service.

The Board of Trustees is gratified to note the progress being made by the Commission on Medical Care Plans in dealing with a most important and complex problem. It acknowledges the tremendous amount of data which have been assembled and analyzed by the Commission. The Board expresses the hope that the Commission will see fit to publish whatever data and information it considers to be of interest and value to the medical profession and the public in order that they, too, may benefit from this exhaustive research, even before final recommendations are arrived at by the Commission.

The Board recognizes the importance of the next phase of the Commission's endeavors; namely, the determination of the effect of these plans on the quality and quantity of medical care provided and the legal and ethical status of the arrangements utilized by the various plans. It is in sympathy with the Commission's recommendation that a suitable consultant be employed to assist in developing a technique to accomplish the objectives mentioned in its report.

The Board recommends, however, that the Commission explore first the possibility of conducting further inquiry by interviews, visits, or some other pilot study technique among a group of representative plans and medical societies. This approach would delineate those areas and elements with which it is concerned and assist it in arriving at criteria for the further evaluation of these plans.

It has been suggested to the Board that a national Congress on Medical Care Plans be held, possibly this Fall, under the sponsorship of the American Medical Association through its Councils on Medical Service and Industrial Health and the Commission on Medical Care Plans. The Board is inclined to favor such a suggestion, since it would provide a common meeting ground at which representatives of all types of medical care plans throughout the country could present valuable information and exchange opinions. The knowledge gained from such a meeting would fill many current informational gaps.

The Board concurs in the Commission's expression of need for a statement of desirable objectives, scope, facilities, and personnel requirements of occupational health programs and is requesting the Council on Industrial Health to undertake this project.

SECOND PROGRESS REPORT OF COMMISSION ON MEDICAL CARE PLANS

Introduction

In its first progress report to the Board of Trustees in October, 1955, the Commission on Medical Care Plans detailed at considerable length the broad scope of the responsibilities delegated to it. It also stated that recommendations would be forthcoming only when its members felt they were in full possession of all facts that would enable them to arrive at conclusions consonant with its stated goals and objectives. This obligation to the medical profession and the public it serves had dictated the necessity for painstaking research and thorough study of all conceivable elements and factors entering into the consideration of (1) the nature and methods of operation of the various types of plans through which persons receive the services of physicians; (2) the effect of these plans on the quality and quantity of medical care provided; and (3) the legal and ethical status of the arrangements used by the various plans.

Status of Research

On April 28 and 29, 1956, the Commission met to review the results of seven distinct areas of research completed by the staff and cooperating organizations over the past six months. Out of the meetings of the full Commission and deliberations of the four committees into which the Commission had been divided, there developed the unanimous feeling that a sufficient amount of statistical data had been developed. Thus, phase 1 of the Commission's objectives, which was the measurement of the major quantitative and historical aspects of its studies, was acknowledged to have been completed. The seven areas of research involved:

1. A detailed study of 305 Miscellaneous and Unclassified Plans (at least two-thirds of which are presumed to fall within the scope of this study) to secure uniform data on structure, method of organization, medical services provided, and other significant characteristics;
2. Analyses of Blue Shield and other Medical Society Approved Plans to produce information on the characteristics of such prepayment mechanisms as well as the payments for the 29 most common surgical procedures;
3. A study of contract provisions of the most widely held and most liberal policies issued by insurance companies writing individual and family surgical and medical expense policies;
4. A similar survey among insurance companies issuing group surgical and medical expense policies;
5. A survey among almost three thousand medical directors of inplant medical programs to determine the characteristics and medical and ethical relationships involved in industry programs;
6. The use of the same study schedule to secure various types of information with regard to occupational disability programs (Workmen's Compensation); and
7. The preparation of a 185 page compilation integrating the policy statements of the House of Delegates with Judicial Council decisions relative to pertinent sections of the Principles of Medical Ethics from 1847 to the present date.

Problems Presented Through Three Areas of Study

Three categories of medical care plans illustrate the nature of the problems to which the Commission must next address itself.

1. *Miscellaneous and Unclassified Plans.*—One hundred and seven plans (other than Blue Shield, Medical Society Approved, commercial insurance, and certain fraternal organizations) covering over 3,500,000 persons, returned the detailed questionnaire. The plans fell into several categories which had been previously defined and classified as cash indemnity, service, closed panel open to the general public, closed panel limited to specific industries, unions, or fraternal groups, or a combination of the foregoing. The returns are considered to be a cross section of the more than 200 plans previously identified by the Commission. They adequately meet the requirements of objective 1 of the Commission's study. They present an adequate sampling of the different programs in existence today. Enrollment, type of sponsorship, eligibility, types of medical services rendered, number of physicians employed on full or part-time basis, organizational structure, and other quantitative elements are clearly detailed.

The Commission next attempted to achieve objectives 2 and 3 by determining (a) what effect, if any, these plans have on the traditional patient-physician relationship, (b) whether the introduction of a third party tends to disturb it and results in an inferior quality of medical care, (c) whether there are plans in which the participating physician is violating the Principles of Medical Ethics, (d) whether these plans will encourage the corporate practice of medicine, and (3) what the proper relationship, if any, will be between the medical profession and these third party mechanisms.

The Commission reports candidly to the Board of Trustees that these questions were difficult to answer. To illustrate the nature of the problem, information provided by four plans, selected at random from among the 107 specially prepared summaries of the returns, was reviewed and evaluated. The Commission was convinced that its opinions, observations, and knowledge of the operations of these plans could not provide the complete answers to these basic questions. It had yet to determine (1) those criteria whereby the quality of medical care can be established and measured, and (2) what are the actual existing ethical and professional relationships.

The Commission believes that a questionnaire survey inevitably reflects the bias of the persons completing the form. For example, a plan may appear to conform to the Principles of Medical Ethics on the survey response, but actually may be rendering an inferior quality of medical care. On the other hand, it is conceivable that although professional relationships and arrangements may appear to indicate violation of the Principles, subsequent study of the local situation and other factors may dispel this impression. In any event it is apparent to the Commission that answers to the basic questions that it has posed will require continued intensive research and investigation.

Recommendation: Faced with the problem of determining how to secure information which does not lend itself to a mail questionnaire technique, the Commission accordingly recommends to the Board of Trustees that a consultant be sought and employed to aid the Commission in developing a project-design to secure the information it deems essential for the further evaluation of this group of Miscellaneous Plans. The elements to be included in such a study are criteria to determine the quality of medical care provided, ethical relationships, and evaluation of medical services by participants in the plans.

2. *Industry Programs Providing Nonoccupational Medical Care.*—The results of the survey of inplant nonoccupational medical programs renders further support to the above recommendation. Data were secured which enabled the Commission to analyze the characteristics of 244 inplant programs providing various forms of medical care to more than 1,440,000 persons. On the basis of information contained in these responses, it appears likely that in certain industrial programs the presence of third parties in varying degrees (a) may affect the traditional patient-physician relationship, (b) may introduce elements which affect the quality and quantity of medical care, and (c) may occasionally raise questions of violations of the Principles of Medical Ethics. Moreover, since a number of medical care programs in industry possess characteristics similar to those in the Miscellaneous and Unclassified category, and inasmuch as appropriate criteria were not available to measure the quality of medical care, the techniques developed through the recommendation already made would undoubtedly assist in reaching some conclusions with respect to plans in industry.

Recommendations:—Based upon the findings of its survey, the Commission recommends that a clear statement of desirable objectives, scope, facilities, and personnel requirements of occupational health programs is needed. Such a statement to supplement the Principles for Evaluating Union and Management Health Centers, which were approved by the House of Delegates in Boston on Dec. 1, 1955, should be prepared by a duly authorized and appropriate committee of the American Medical Association.

The Commission calls attention to the fact that among the various findings of the survey there is revealed the presence of a specific problem area involving relationships between the medical director in inplant programs and the general practitioner.

3. *Occupational Disability Programs—Workmen's Compensation.*—The findings of this survey lend further substantiation to the statements regarding major issues in compensation which were presented in the first progress report. These issues are (1) choice of physician; (2) supervision of medical treatment; (3) supervision of medical costs; (4) medical testimony; and (5) rehabilitation.

In this area of study, too, the Commission felt that it did not have appropriate criteria for measuring the quality of medical care, except in so far as statutory limitations of workmen's compensation laws affect the quality. The Commission understands that the Council on Industrial Health is conducting studies of these programs.

Conclusion

The Commission has accumulated sufficient quantitative data in connection with its various areas of study. Its next task is to develop a plan for eliciting the information with respect to objectives 2 and 3 that has not yet become available. Continuing evaluation and refinement of the material collected to date will take place at future meetings of the Commission.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. John K. Glen, Chairman, Texas, read the following report, which was adopted:

Supplementary Report of Board of Trustees B.—Your reference committee considered supplementary report of the Board of Trustees B on Progress Report of Commission on Medical Care Plans, presented by Dr. Leonard W. Larson, Trustee and Chairman of the Commission. Your committee recommends the acceptance of this report and of the progress report of the Commission, and wishes to commend the Commission on its excellent progress as reported.

C. Progress Report of Committee on Legislation

This report covers the period from Sept. 1, 1955, to June 1, 1956. It includes activities of the Committee in preparation for the 2d Session of the 84th Congress, which convened in January, 1956, as well as the activities of the Committee during the session. During the period covered by this report, the Committee met three times, in Boston, Washington, and Chicago. A detailed outline of the Eisenhower administration's health program was presented to the Committee by Assistant Secretary of Health, Education and Welfare Roswell B. Perkins. Important new bills were considered for the first time, and modified versions of previous legislation were reconsidered. Methods of implementing the Association's position on all of these measures were discussed. This report pictures the most significant developments during the period.

REGIONAL LEGISLATIVE CONFERENCES

As part of the continuing effort of the Committee to establish closer and more effective liaison with state and local medical societies and individual members of the Association, six Regional Legislative Conferences were held in the fall of 1955. Each conference lasted a full day and included discussion of the organization and operation of the Association's legislative program, proposed federal health re-insurance and mortgage loan guarantees, treaties and their effect on the practice of medicine, veterans' medical care, tax-deferred retirement plans for physicians, current problems in military medicine, federal aid to medical education, and disability benefits under Title II of the Social Security Act.

One of the most important features of these conferences was the opportunity afforded participants to express their own views on these subjects and to ask critical questions of members of the Committee and the Association staff. The Committee feels that such conferences are of great value in alerting the leaders of state and county units of organized medicine to legislative developments of national significance and in obtaining more effective support of medicine's legislative objectives. Proceedings of each conference were distributed to all participants and, on request, to many physicians unable to attend. The conferences provided the basis for discussion of national legislation in local and state meetings, and parts of the proceedings have been widely reprinted in state medical journals and county bulletins.

PERMANENT AND TOTAL DISABILITY BENEFITS

The major legislative activity of the Association during the period covered by this report dealt with the proposal to pay cash disability benefits under Title II of the Social Security Act to covered individuals at the age of 50. This measure passed the House of Representatives in July, 1955, with no hearings, virtually no debate, and by an overwhelming vote of 372 to 31. It was apparent from the outset that the political appeal of this proposal, particularly in an election year, would make it extremely difficult to defeat.

During the fall of 1955, members of the Committee on Legislation, assisted by members of the headquarters staff and personnel from the Washington Office, met with the leaders of medicine in fifteen key states to organize effective opposition at the state level. Analyses of H. R. 7225 explaining its full implications were prepared and circulated widely within and without the profession.

Early in December, Dr. Elmer Hess, as President, wrote to every member of the Association outlining the dangers inherent in the measure and requesting assistance in explaining these dangers to members of the Congress. The response of individual physicians and medical organizations has been both heartening and effective. Never in recent years has the profession been so nearly unanimous on a subject. These efforts were instrumental in impressing members of the Senate with the dangerous implications of the disability benefit proposal.

Medical testimony on H. R. 7225 was heard by the Senate Finance Committee on Feb. 9, Feb. 22, and Feb. 23, 1956. Dr. David B. Allman and Dr. F. J. L. Blasingame presented the testimony of the Association on Feb. 23. Witnesses representing 17 state associations, 3 county societies, and 5 other medical organizations were heard by the Committee. The witnesses, consisting of physicians engaged in general practice and specialists in virtually every branch of medicine presented a well-rounded picture of the medical problems in determining disability and treating patients with physical or mental impairments.

Fortunately the Eisenhower administration and a substantial majority of the Senate Finance Committee opposed the provision of cash disability benefits under Title II of the Social Security Act. After hearings lasting several months, the Committee voted 11 to 4 to remove this feature from the measure. On May 25, H. R. 7225, with the disability benefit section deleted, was reported to the Senate. The debate on this bill is probably starting either this morning or it will start tomorrow morning in Congress, in the Senate, and it will be a determined effort to reinstate the disability provision in this bill. Of course, we do not know how long this debate is going to last. The vote may be taken this week or it may be delayed for a week or a month.

MILITARY MEDICINE

At the time of the extension of the "Doctor-Draft" law in June, 1955, the Association recommended to Congress that steps be taken to correct the basic causes for physician shortages in the armed services. A major portion of the legislative activities in which the Committee has engaged during the period covered by this report relates to measures designed to carry out these recommendations.

Studies made in the Department of Defense, prompted in part by the insistence of the Association that corrective action be taken, led to the introduction of legislation substantially improving the status of military medical officers. The Association vigorously supported enactment of this proposal and the restoration of the increased incentive pay originally recommended by the Department of Defense but deleted by the Bureau of the Budget. That pay was in part restored and the Career Incentive Bill passed the House. Upon the strong recommendation of witnesses for the Association, the additional incentive pay was further increased by the Senate, and the Career Incentive Act became law on April 30, 1956. It is believed that this legislation will provide the basis for a sounder approach to the medical manpower problems of the armed services.

The Department of Defense also supported the enactment of a bill to authorize medical care for military dependents in both military and civilian facilities. The original version of this bill was heavily weighted to favor the utilization of military facilities. As a partial result of the testimony presented by the Association before the House Armed Services Committee and the work of the Washington Office, a greatly improved Dependent Medical Care Bill was passed in March. The Senate passed an amended version of the bill and a version compromising the differences between the House and the Senate bills was reported by a conference committee and subsequently adopted. The new Dependent Care Bill requires the Secretary of Defense to contract for medical care for dependents but does not spell out the particular type of program to be followed in utilizing the service of civilian physicians. The amended and improved version of the bill finally came out and became law on June 7, 1956, and is known as Public Law No. 569.

The Committee on Legislation has vigorously opposed a House measure authorizing the appointment of osteopaths as military medical officers. As this bill passed the House last July, it would have required the Armed Services to commission osteopaths. The Senate added an amendment requiring that the Surgeon General of the appropriate service specifically approve the appointment of any osteopath. The House has not agreed to accept the Senate changes, so we still do not know as of today just exactly what will happen there.

MISCELLANEOUS LEGISLATION

The Committee on Legislation has been active in connection with numerous other bills. Among these measures are the Jenkins-Keogh bills; legislation relating to federal participation in the construction and maintenance of state soldiers' homes; the authorization of a National Morbidity Survey; the Alaska Mental Health bill; federal aid to medical education and research facility construction; military status of the Public Health Service commissioned corps in time of emergency; Congressional inquiries on narcotics, barbiturates, and amphetamines; the Water Pollution Control Act Extension; and various appropriations, including Civil Defense medical appropriations, Poliomyelitis Vaccination Assistance Act appropriations, and appropriations for the continuation of the Veterinary Corps in the Army and the Air Force. Oral testimony or letters and statements explaining the Association's views have been presented on all of these measures to appropriate committees of the Congress. In addition to furnishing assistance to the 29 witnesses who appeared before the Senate Finance Committee on H. R. 7225, 12 other witnesses have appeared on behalf of the Association before various committees during the period covered by this report. On 22 occasions the views of the Association have been presented to committees by means of written statements.

Since activity is considerably accelerated during the closing days of Congress, the final action on many of the foregoing measures is unknown. At the time of the preparation of this report, however, the status of the principle measures is as follows:

The Jenkins-Keogh bills have been approved by the House Committee on Ways and Means, but not yet reported to the floor of the House. Strong sentiment for their enactment has been expressed by nearly one-fourth of the members of Congress.

The National Morbidity Survey Bill and the Water Pollution Control Act Extension have passed the Senate and have been favorably reported in the House.

The Alaska Mental Health Bill has passed the House and has been favorably reported in the Senate.

The Public Health Service Status Bill has become law.

CONCLUSION

In closing this report, it is particularly fitting to note the Committee's profound appreciation for the invaluable assistance received from the Board of Trustees, the Washington Office, the Woman's Auxiliary, the officers and staff of the Association, and state and county medical societies. The keen interest and effective cooperation of an ever-increasing number of individual physicians has been a source of great satisfaction to the Committee, for which the members are profoundly grateful.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. Willis H. Huron, Chairman, Michigan, read the following report, which was adopted:

Supplementary Report of Board of Trustees C on Progress Report of Committee on Legislation.—This report was covered in detail. Your committee recognizes the value of the regional legislative conferences. It believes, however, that the work of the Committee could be even more effective if a representative of the Committee could appear before the House of Delegates and representative members of each state society to discuss legislative matters on a national level. Your reference committee wishes to compliment the Chairman of the Committee on Legislation for his progress report and to commend the Committee for its continued fine work.

D. MEDICAL HALL OF FAME

Supplementary report D was referred to the Reference Committee on Miscellaneous Business.

Resolution No. 25 (Atlantic City, 1955) recommending a study of the establishment of a Medical Hall of Fame in the United States was reviewed by the Board of Trustees. In its study several factors relating to expense, available space, and similar projects already established by the federal government and other bodies were disclosed. The Board requests, therefore, that it be permitted to continue its investigation of the matter with the hope that a definite report will be available at the Clinical Meeting in Seattle.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Joseph C. Griffith, Chairman, Wisconsin, presented the following report, which was adopted:

Supplementary Report of Board of Trustees D on Medical Hall of Fame.—This supplementary report concerned a study of the establishment of a Medical Hall of Fame. The Board requests permission to continue its investigation as to expense, available space, etc., with a report to be made at the Clinical Meeting in Seattle. Your reference committee agrees.

E. Neoplastic Diseases

Supplementary report E was referred to the Reference Committee on Hygiene, Public Health, and Industrial Health.

The Council on Industrial Health, at its meeting in January, 1956, called attention to the fact that statistical information is needed for comparing cancer in the industrial population with that in the general population. It believes that the excellent study recently made by the Division of Occupational Health and the National Cancer Institute of the Public Health Service should be a continuing study, reported every few years.

The Council further stated that the natural occurrence of diseases in the United State fluctuates over the years as the result of many factors. The effective treatment of infection, decline in neonatal mortality and various other advances in American medicine have increased life expectancy, thereby emphasizing the medical, social, and economic importance of chronic diseases. Inasmuch as malignant neoplasms form an increasingly important segment of medical practice, a need for continuing evaluation of progress in the management of clinical cancers requires accurate statistics of the incidence of specific anatomical types of malignant neoplasms in relation to age and sex. Investigation of the incidence of cancer in association with exposure to environmental hazards requires standardized rates of risk to specific anatomical types of cancer in relation to age and sex as accurate standards of reference for comparison with specific types of exposure.

The Council recommends, therefore, and the Board concurs in this recommendation, that the agencies already concerned with compiling vital and health statistics on the morbidity and mortality of neoplastic diseases be encouraged to continue and expand their activities in this field as a major and important contribution to the control of cancer.

REPORT OF REFERENCE COMMITTEE ON HYGIENE, PUBLIC HEALTH, AND INDUSTRIAL HEALTH

Dr. Martyn A. Vickers, Chairman, Maine, submitted the following report, which was adopted:

Neoplastic Diseases.—This deals with a study recently made by the Division of Occupational Health and the National Cancer Institute of the Public Health Service, and it recommends continued cooperation of these agencies in compiling vital statistics of the morbidity and mortality of neoplastic diseases and expand their activities in the field as a major and important contribution to the control of cancer.

F. American Medical Association Dues

Supplementary report F was referred to the Reference Committee on Reports of Board of Trustees and Secretary.

The Board of Trustees referred to its Finance Committee the recommendation of the House of Delegates (Boston, 1955) that consideration be given to a dues increase for the benefit of the American Medical Education Foundation and for other purposes. At its meeting on May 19, 1956, the Finance Committee thoroughly discussed the recommendation from the House of Delegates. The following report was submitted to the Board and was approved for presentation to the House:

In view of the fact that income was in excess of expense for 1955, the Finance Committee feels that it cannot recommend that an increase in dues be proposed to the House of Delegates at this time. However, because of the increased activities being undertaken by the Association's councils, committees, and departments, it is getting more and more difficult to balance the budget and a probable increase in dues must be faced. If the activities of the Association continue to expand over those of the past year, as all trends indicate, either the Association activities will have to be curtailed or the state associations must undertake more of these responsibilities. The Finance Committe recommends that the following action taken by the House of Delegates in June, 1955 be reiterated:

> Your Reference Committee (on Reports of Board of Trustees and Secretary) is in hearty accord with the suggestion to the House in this and future sessions that each delegate seriously consider organizational, financial, and personnel problems involved when they recommend that a new council or study committee be formed for this or that activity.

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Dr. Woodruff L. Crawford, Chairman, Section on Pediatrics, presented the following report, which was adopted:

Supplementary Report of Board of Trustees F on American Medical Association Dues.—Your reference committee approves of this statement of the Board of Trustees.

G. Professional Liability Insurance

Supplementary report G was referred to the Reference Committee on Reports of Board of Trustees and Secretary.

The Board of Trustees considered the following report of the Law Department relative to its study of professional liability insurance and claims prevention programs, in which the Council on Medical Service concurs, and with its approval submits it to the House of Delegates for consideration.

STUDY OF PROFESSIONAL LIABILITY INSURANCE AND CLAIMS PREVENTION PROGRAMS

In accordance with the request of the Board of Trustees and the House of Delegates, the Law Department has continued its study of Medical Professional Liability. Some of the activities mentioned in the report of Nov. 21, 1955, have been initiated, others have been completed.

Opinion Survey.—A questionnaire, designed to obtain the opinion of individual physicians concerning professional liability, has been pretested. During the month of June it will be sent to a random 5% sample of Association members. The responses should give an indication of the number of claims and suits that have been brought against physicians, the amount of professional liability insurance carried by physicians, the percentage of physicians who carry professional liability insurance, and a consensus as to the best way to cope with professional liability claims and suits. All of this information will be broken down by age group, medical specialty, and geographical location.

Analysis of Reported Cases.—An analysis of all the reported cases for the past 20 years for every state is about 80% completed. It is estimated that when this project is finished, about 750 cases will have been reviewed. It is expected that these cases will disclose a wealth of information, and indicate the legal trends in the various states.

Preparation and Publication of Special Articles.—Eleven physicians and attorneys have been asked to write articles on various aspects of medical professional liability. It is planned to publish each article in a separate issue of THE JOURNAL. Thereafter all the articles will be reproduced in booklet form.

Insurance Experience and Rates.—Thirty-one of the known insurance companies writing professional liability insurance in this country have been contacted and requested to cooperate with the Law Department in this study. These companies have been asked to supply extensive statistical data relative to professional liability claims and suits filed. To date, with the assistance of the Council on Medical Service and the National Bureau of Casualty Underwriters, liaison has been established with 10 companies. Other carriers will be contacted within the next two months. These insurance companies can make an invaluable contribution to this study by furnishing information which to date has not been available on a national basis.

Statutes of Limitations.—A detailed study of the statutes of limitations of each state relating to medical professional liability suits has been completed.

Professional Liability Claims Involving Physicians in Government Service.—Letters have been sent to the armed forces, Veterans Administration, Public Health Service, and Department of Justice in an effort to obtain information on the causes, number and disposition of professional liability claims and suits against government physicians, as well as the role the government plays in assuming responsibility. Generally speaking, the legal principles governing professional liability of civilian physicians are equally applicable to government physicians. Simply stated, the government physician is personally responsible for negligence that results in injury to his patients in the same manner and to the same extent as if he were in private practice. If, however, the injured patient elects to proceed against the United States under the Federal Tort Claims Act and receives a judgment against the United States, the physician is relieved from pecuniary liability. Because of the guarantee of solvency and the relative ease of collectability of judgments against the government, professional liability suits are usually brought against either the government alone, or the Government as a co-defendant with the physician.

Conclusion.—The Law Department has obtained fine cooperation from those who have been asked to assist it. If this spirit continues, the Director of the Department is confident that answers to most of the questions on professional liability which physicians have been asking for many years will be obtained.

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Dr. Woodruff L. Crawford, Chairman, Section on Pediatrics, read the following report, which was adopted:

Professional Liability Insurance.—Your reference committee considered the report of the Law Department relative to its study of Professional Liability Insurance and Claims Prevention Program, in which the Council on Medical Service concurs. It was pointed out in discussion that Alaska and Hawaii were not included in the survey, but your committee feels that they should be. Your committee hopes the constituent associations will lend their efforts to help the Law Department to clarify this vexing problem. Inasmuch as the report is merely a progress report of information, no action need be taken at this time.

H. Areas of Understanding

Supplementary report H was referred to the Reference Committee on Insurance and Medical Service.

The following report, approved by the Council on Medical Service, was considered by the Board of Trustees and approved for submission to the House of Delegates:

The Committee on Federal Medical Services has studied and reviewed the proposed statement concerning VA medical affairs and the ten areas of possible understanding between the American Medical Association and the American Legion in accordance with the letter of March 30, 1956, addressed to the Council on Medical Service from the Board of Trustees. The Committee is of the opinion that the American Medical Association and the American Legion should continue to cooperate in an effort to provide the finest medical care for all segments of the American public, with special emphasis on the obligations of a grateful nation toward those who have suffered disability as a result of military service. It is the further recommendation of the Committee that both organizations should join in aggressively seeking an adequate program of prevention and treatment of mental disorders. The Committee has found no reason to suggest revision of the fundamental American Medical Association concept that it is contrary to the public interest to approve VA medical care for disability unrelated to military service. In consequence it feels that those suggested areas of understanding which conflict with this position cannot be endorsed.

The Committee recommends that the members and staff of the Liaison Committee be thanked for their efforts and activities and that the Committee on Federal Medical Services be authorized to make a continuing study of all aspects of VA medical activities under the basic policy established by the American Medical Association House of Delegates in June, 1953.

The Board of Trustees calls attention to the fact that the special Liaison Committee was discharged on Feb. 11, 1956.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. John K. Glen, Chairman, Texas, submitted the following report, which was adopted:

Supplementary Report of the Board of Trustees H on Areas of Understanding.—Your reference committee gave long audience to those who would inform it on this matter. After due deliberation, your committee recommends approval of this report with the following addendum to follow the words "in June, 1953," in the next to the last paragraph of the report: "Inasmuch as the 1953 policy of the American Medical Association House of Delegates adds certain temporary exceptions in respect to the Veterans Administration care of nonservice-connected disabilities, such as those of neuropsychiatric or tuberculous origin, it is recommended that a reconsideration of these temporary exceptions be made by the Council on Medical Service, through its Committee on Federal Medical Services, with a view to adjusting these exceptions in more realistic fashion to the needs of areas in this country where local facilities do not exist for the care of mental disease, tuberculosis, and other chronic disabilities as well."

I. National Civil Defense

Supplementary report I was referred to the Reference Committee on Medical Military Affairs.

The following report was received by the Board from the Council on National Defense and was approved for submission to the House of Delegates for its consideration and action:

The continued existence of our nation and the survival of our people depend upon a complete and effective national defense on both the military and civilian level. Inasmuch as the existence of weapons which release energy equivalent to millions of tons of TNT is now a fact, an enemy attack employing thermonuclear weapons in the megaton range could result in millions of our citizens being killed or injured. The effective handling of mass casualties following such an attack requires new procedures and medical skills using every physician and all ancillary personnel in the country.

It is therefore the solemn duty of the medical profession, including every individual physician in the country, to exercise his skills, knowledge, and best judgment to prevent human suffering and loss of life and to assume responsibility for solution of the complex medical problems arising from instantaneously produced mass casualties.

The Council and the Board of Trustees recommend that the House of Delegates express its grave concern over the present inadequacy of our national civil defense effort. An efficient and practical medical civil defense should be developed by the best minds in our nation as an absolute necessity to national survival, and the physicians of our country, individually and in associated bodies, must assume the basic responsibility of preparing for and assuming the management and care of mass casualties during a grave national disaster. The Board of Trustees recommends further that the Council on National Defense study and report on a plan and organization by which the medical profession can be mobilized to meet the current and future need for an adequate national medical civil defense preparedness plan.

REPORT OF REFERENCE COMMITTEE ON MEDICAL MILITARY AFFAIRS

Dr. William C. Chaney, Chairman, Tennessee, presented the following report, which was adopted:

National Civil Defense.—In considering supplementary report I of the Board of Trustees your committee is impressed with the serious and important responsibilities of the Council on National Defense with respect to its activities concerning medical disaster preparedness and emergency medical services. Your committee agrees with the Council and the Board of Trustees that the continued existence of our national and the survival of our people depend upon a complete and effective national defense on both the military and civilian levels. This committee is convinced that an enemy attack employing thermonuclear weapons could result in millions of our citizens being killed or injured, and that the effective handling of mass casualties following such an attack requires new procedures and medical skills using every physician and all ancillary personnel in the country.

Your committee believes it is the solemn duty of each individual physician to exercise his skills, knowledge, and best judgment in preventing human suffering and loss of life. Therefore, physicians should assume responsibility for solution of the complex medical problems arising from instantaneously produced mass casualties. Your committee endorses the proposition that an efficient and practical medical civil defense should be developed by the best minds in our nation as necessary to national survival.

Your committee received with interest the statements from members of the Council pertaining to studies and plans that are currently in progress: (1) to assist state medical societies in promoting and developing active programs for emergency medical services; (2) to obtain information on the emergency care of casualties by specialty groups; (43) to act as a liaison with these groups to aid them in defining their role so that a comprehensive emergency medical service program can be realized; and (4) to define and integrate the special medical training for allied medical and health groups. Your committee commends the Council on its accomplishments, and is impressed with its grasp of the problem. Your reference committee recommends that the Council on National Defense complete its plan for an organization by which the medical profession can be mobilized to meet the current and future need for an adequate national medical civil defense program.

J. Veterinary Corps

Supplementary report J was referred to the Reference Committee on Medical Military Affairs.

The following recommendation of the Council on National Defense was approved by the Board of Trustees for submission to the House of Delegates:

The Congress legislated to establish the Army Veterinary Corps in the National Defense Act of June 3, 1916, and reaffirmed its action in the Army Organization Act of 1950, and the United States Air Force recognized the military necessity for a veterinary service and administratively established a Veterinary Corps in 1949.

Military veterinarians have made and continue to make valuable contributions to medical science of both military and civilian significance. They have played a vital role in successfully protecting the health of troops from food-borne and animal diseases throughout two world wars and the Korean conflict and currently are responsible for inspection of food used by the Armed Forces. The professional capabilities, military training, and centralized control of the Army and Air Force Veterinary Corps have established them as indispensable components of the over-all preventive medicine program and as important paramedical elements in the event of atomic disaster. The officers of this corps, trained and being trained in radiobiology, radiotoxicity, and radioassay as these pertain to foodstuffs and food-producing animals subjected to the effects of nuclear detonations, comprise a group whose technical knowledge and capabilities will be of inestimable value to both military and civilian populations in the event of atomic disaster and would be difficult of replacement. Officers of the Army and Air Force Veterinary Corps, trained and being trained in the medical care of human casualties, are being relied upon to assist medical officers in the event of atomic disaster. The elimination of military veterinarians will substantially increase the armed forces' requirements for medical officers to assume many of the functions performed by the former and thereby reduce the number of physicians available for the medical care of the civilian population. The Council on National Defense believes that the proposal of the Secretary of Defense would deprive the Armed Forces of important operational elements that function to protect the health of our soldiers, sailors, and airmen at home and overseas, and recommends therefore that the American Medical Association vigorously oppose any action by the Department of Defense that would "reassign, discontinue, or obtain through contractural arrangements the various functions performed by the Army and Air Force Veterinary Corps."

REPORT OF REFERENCE COMMITTEE ON MEDICAL MILITARY AFFAIRS

Dr. William C. Chaney, Chairman, Tennessee, read the following report, which was adopted:

Your reference committee approves in principle supplementary report J pertaining to the military Veterinary Corps. Your committee notes that the Congress legislated to establish the Army Veterinary Corps in the National Defense Act of June 3, 1916, reaffirmed its action in the Army Organization Act of 1950. The United States Air Force recognized the military necessity for a veterinary service and administratively established a Veterinary Corps in 1949.

Military veterinarians have made and continue to make valuable contributions to medical science of both military and civilian significance. They have played a vital role in successfully protecting the health of troops from food-borne and animal diseases throughout two World Wars and the Korean conflict, and currently are responsible for inspection of food used by the armed forces. The professional capabilities, military training and centralized control of the Army and Air Force Veterinary Corps have established them as indispensable components of the overall preventive medical program and as important supporting medical elements in the event of atomic disaster. Your committee further notes that the officers of this Corps, trained in radiobiology, radiotoxicology, and radioassay which pertain to foodstuffs and food producing animals subjected to the effects of nuclear detonations, comprise a group whose technical knowledge and capabilities will be of inestimable value to both military and civilian populations in the event of atomic disaster and would be difficult of replacement. Officers of the Army and Air Force Veterinary Corps, trained and being trained in the medical care of human casualties, are being relied upon to assist medical officers, in the event of atomic disaster. Your committee is impressed with the contention that the elimination of military veterinarians will substantially increase the Armed Forces' requirements for medical officers to assume many of the functions performed by the former and thereby reduce the number of physicians available for the medical care of the civilian population.

For these reasons, your committee recommends that this House of Delegates oppose the elimination of military veterinarians. Your committee further recommends that a copy of the report and action be sent to the President of the United States, members of the Armed Services Committees and Appropriations Committees of the Senate and House of Representatives, including telegraphic copies to the Secretary of Defense and the Surgeons General of the Army, Navy, and Air Force.

Report of Committee to Review the Functions of the Joint Commission on Accreditation of Hospitals

Dr. Wendell C. Stover, Chairman of the special Committee to Review the Functions of the Joint Commission on Accreditation of Hospitals, presented the following report, which was referred to the Reference Committee on Medical Education and Hospitals.

At the annual meeting of the House of Delegates in June, 1955, the following resolutions relating to the Joint Commission on Accreditation of Hospitals were introduced: Resolution No. 3 on Accreditation of Hospitals, introduced by Dr. Joseph B. Copeland on behalf of the Texas delegation; Resolution No. 15 on Accreditation of Hospitals, introduced by Dr. James Q. Graves for the Louisiana delegation; Resolution No. 17 on Board of Mediation for Joint Commission on Accreditation of Hospitals, introduced by Dr. George F. Gsell on behalf of the Kansas delegation; Resolution No. 20 on Activities of Joint Commission on Accreditation of Hospitals, introduced by Dr. George A. Unfug on behalf of the Colorado delegation; Resolution No. 59 on Hospital Accreditation, introduced by Dr. John F. Burton on behalf of the Oklahoma delegation; and Resolution No. 67 on Accreditation of Hospitals, introduced by Dr. Elmer P. Weigel on behalf of the New Jersey delegation.

The above-named resolutions were considered by the Reference Committee on Medical Education and Hospitals, which made the following recommendations:

". . . that the Speaker of the House of Delegates be requested to appoint a special committee to review the functions of the Joint Commission on Accreditation of Hospitals to consist of seven members, none of whom shall be members of the Council on Medical Education and Hospitals or of the Joint Commission on the Accreditation of Hospitals. This special committee should be instructed to make an independent study or survey and report its findings and recommendations to the House of Delegates at the next annual meeting. All physicians and hospitals are urged to pass on to this special committee any observations or suggestions concerning the functioning of the Joint Commission on Accreditation of Hospitals."

Two resolutions introduced in the House, December, 1955, by Dr. Clark Bailey for Kentucky were also referred to the Committee.

Committee Procedure

As a result of this directive by the House, the Speaker appointed a seven-man committee which has held five meetings with 100 per cent attendance by the members.

Letters and Publicity.—To obtain as much factual data as possible and to give physicians and hospital administrators throughout the country an opportunity to express their views on the functions of the Joint Commission letters were sent to state medical associations and large component medical societies, and to the American Hospital Association for distribution to state hospital associations. Notices and news items were published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and the Secretary's Letter. These letters and news items informed physicians and medical organizations of the creation of the Committee and requested them to notify their members—through journals, bulletins, newsletters, or a special mailing to their memberships—of the Committee's desire for information on the following:

1. The general understanding by physicians of the functions of the Joint Commission.
2. Whether the method of appeal from an adverse ruling regarding accreditation is satisfactory.
3. The effect on the individual physician's hospital connections due to actions of the Joint Commission.
4. Whether any organizations not now represented should have official representation on the Joint Commission.
5. The effect of the Joint Commission's requirements concerning such matters as staff meetings.
6. The pros and cons of separating administrative and professional accreditation functions in the inspection of hospitals.
7. Constructive suggestions for improving the hospital accreditation program.

Interviews.—To obtain background information the Committee, at its various meetings, interviewed (1) the Director and staff of the Joint Commission at the Commission's offices; (2) representatives and some of the Commissioners of the American Medical Association, American Hospital Association, American College of Surgeons, and American College of Physicians; (3) representatives of the American Academy of General Practice, including national officers and state delegations; and (4) surveyors of the member organizations of the Joint Commission. A detailed letter was also received from the Canadian Medical Association.

As a result of its studies the Committee found that the dissatisfaction with the functions of the Joint Commission, as intense as it is in some localities, is not as widespread geographically as this Committee had been led to believe. It is also evident that much of the criticism is based on misunderstanding and misinformation.

History of Accreditation

A Hospital Standardization Program was begun by the American College of Surgeons in 1920 the purpose of which was ". . . to create in the hospital an environment which will assure the best possible care of the patient." The American College of Surgeons conducted this program until December, 1951, when it became too expensive, at which time they proposed to turn it over to the American Hospital Association. The American Medical Association then took definite action and it was agreed that both medical and hospital groups should be represented in the program. On December 15, 1951, the Joint Commission on Accreditation of Hospitals was established.

Make-Up of the Joint Commission

The Joint Commission is an independent entity incorporated under the laws of the State of Illinois as a nonprofit corporation. As a separate corporation it functions within the limitations of its articles of incorporation, which set forth its charter powers, and the bylaws of the corporation, which enumerate its activities and plan of organization. The American Medical Association is a member organization of the Joint Commission in common with other member organizations.

According to the Bylaws of the Joint Commission on Accreditation of Hospitals, Article IV, Section 1, "The Members of this corporation shall be American College of Physicians, American College of Surgeons, American Hospital Association, and American Medical Association." A subsequent amendment authorized membership of the Canadian Medical Association.

Article IV, Section 2, of the bylaws states: "Additional organizations may be admitted to membership in this corporation upon the written approval of all members."

Article VI, Section 1, of the bylaws specifies that, "The affairs of the corporation shall be managed by a Board of twenty (20) Commissioners."

At present the Board of Commissioners consists of the following:

BOARD OF COMMISSIONERS
Chairman, LeRoy H. Sloan
Vice Chairman Julian P. Price
Treasurer, Mr. Stuart K. Hummel
Secretary, Kenneth B. Babcock

AMERICAN COLLEGE OF PHYSICIANS
*1956—Willis M. Fowler, Iowa City
1957—LeRoy H. Sloan, Chicago
1958—Alexander M. Burgess, Providence, R. I.

AMERICAN COLLEGE OF SURGEONS
1956—Walter C. MacKenzie, Alberta, Canada
1957—Warren H. Cole, Chicago
1958—John I. Brewer, Chicago

AMERICAN HOSPITAL ASSOCIATION
1956—Hon. John Milton George, Q. C., Manitoba, Canada
1956—Mr. Stuart K. Hummel, Milwaukee
1956—Jack Masur, Washington, D. C.
1957—Frank R. Bradley, St. Louis
1957—Rt. Rev. Msgr. Donald A. McGowan, Washington, D. C.
1958—Mr. Ray E. Brown, Chicago
1958—Albert W. Snoke, New Haven, Conn.

AMERICAN MEDICAL ASSOCIATION
1956—Dwight H. Murray, Napa, Calif.
1956—Herman G. Weiskotten, Skaneateles, N. Y.
1957—Gunnar Gundersen, LaCrosse, Wis.
1957—Stanley R. Truman, Oakland, Calif.
1958—Julian P. Price, Florence, S. C.
1958—Raymond F. Peterson, Butte, Mont.

CANADIAN MEDICAL ASSOCIATION
1957—E. K. Lyon, Ontario, Canada

ADVISORY COMMITTEE
LeRoy H. Sloan, American College of Physicians
Paul R. Hawley, American College of Surgeons
Edwin L. Crosby, American Hospital Association
George F. Lull, American Medical Association
A. D. Kelly, Canadian Medical Association
Kenneth B. Babcock, Chairman, Joint Commission on Accreditation of Hospitals

---

*Designates year appointment terminates

As the term of each Commissioner expires the Member organization reappoints him or selects a replacement. In the case of the American Medical Association these Commissioners are appointed by the Board of Trustees.

Article VII, Section 1, of the bylaws states: "The officers of the corporation shall be a Chairman, a Vice Chairman, a Secretary and a Treasurer and such other officers as the Board may authorize, all of whom, *except the Secretary, shall be elected from members of the Board of Commissioners.*" These officers are elected at each annual meeting of the Board.

Article VIII, Section 1, of the bylaws states: "There shall be an Advisory Committee composed of the chief administrative officer of each Member or such other person as the Member may designate, and the Director of this corporation. The Director shall act as Chairman of the Advisory Committee."

The expenditures of the Commission for 1955 were $96,192.69. Appropriations by the parent organization are prorated according to the proportion of members on the Commission: American Medical Association, 6/20ths; American Hospital Association, 7/20ths; American College of Surgeons, 3/20ths; American College of Physicians, 3/20ths; and Canadian Medical Association, 1/20th.

In addition, surveyors are employed by each individual Member organization, and they are supplied in the following proportion: American College of Surgeons, 4; American Hospital Association, 5 (including 2 part-time); American Medical Association, 10 (including 2 part-time); and Canadian Medical Association, 2. The surveyors for the American Medical Association also survey residency and internship programs, and the surveyors for the American College of Surgeons survey cancer clinics.

The Committee is cognizant of the fact that the Joint Commission is a relatively new organization and is still in a state of evolution. As new problems arise, improvements in the operations of the Commission are made. For example, recently a major change was made in the survey report forms by eliminating the "point scores."

The Committee is conscious of the importance and prestige of hospital accreditation by the Joint Commission, specifically in those areas of the country where emphasis is placed upon accreditation by Blue Cross, insurance companies, and other agencies, such as the United Mine Workers Welfare and Retirement Fund.

Standards for Hospital Accreditation

Since many members of the House have probably not had an opportunity to review the "Standards for Hospital Accreditation," the Committee believed it important to reproduce the latest revision in its entirety. The following are the standards for hospital accreditation as revised and published by the Commission on January 28, 1956.

BASIC PRINCIPLES

The following outlines the basic principles necessary for accreditation of a hospital by the Joint Commission on Accreditation of Hospitals. They are arranged in three sections according to the major functional divisions of a hospital.

I. ADMINISTRATION

Physical Plant—The buildings of the hospital must be constructed and arranged to insure the safety of the patient and promote his welfare.

Governing Body—The governing body has the legal and moral responsibility for the conduct of the hospital as an institution. It is responsible to the patient, the community, and the sponsoring organization. Its official representative is the chief administrative officer of the hospital.

Facilities for the following services are essential:

Dietary
Medical Records
Pharmacy or Drug Room
Clinical Laboratory, and pathological services
Radiology
Medical Library

II. MEDICAL STAFF

The medical staff is responsible to the patient and to the governing body of the hospital for the quality of all medical care rendered to patients in the hospital and for the ethical and professional practices of its members.

III. NURSING

There must be a graduate registered nurse on duty at all times and professional nursing care must be available for all patients at all times.

STANDARDS FOR METHODS OF PROCEDURE

I. ADMINISTRATION

A. Physical Plant

The buildings of the hospital must be solidly constructed with adequate space and safeguards for each patient. Space provided shall not be less than required by existing legal codes The hospital shall provide:

1. Fire protection by installation of rigid controls and written fire control plans, the elimination of fire hazards, the installation of necessary safeguards such as extinguishers, sprinkling devices, fire barriers, etc., to insure rapid and effective fire control.
2. A sanitary environment to avoid sources and transmission of infections.
3. Facilities for isolation of patients with communicable diseases, especially in obstetrical, newborn, and pediatric sections.
4. Emergency lighting in operating, delivery and emergency rooms, nursery and stairwells.
5. Adequate diagnostic and therapeutic facilities.

B. Governing Body

The governing body is legally and morally responsible for the conduct of the hospital. In the discharge of its duties, it places the responsibility for the medical care of the patient in the hospital primarily upon the medical staff. For effective performance the governing body should do the following

1. Adopt bylaws in accordance with legal requirements
2. Meet at regular stated intervals.
3. Appoint committees. There should be an Executive Committee and others as indicated for special purposes
4. Establish a formal means of liaison with the medical staff preferably by a Joint Conference Committee.
5. Appoint members of the medical staff.
6. Appoint a qualified hospital administrator who is the official representative of the governing body. The administrator is responsible for the conduct of the hospital, and provides liaison among the governing body, the medical staff, the nursing staff, and other departments of the hospital.

C. Essential Services which must be maintained.

1. *Dietary Department*
   a. There shall be an organized department directed by qualified personnel and integrated with other departments of the hospital.
   b. Facilities shall be provided which meet the requirements of the local sanitary code for the storage, preparation, and distribution of food for the general dietary needs of the hospital. These shall include facilities for the preparation of special diets.
   c. There shall be a qualified dietitian on full time or on a consultation basis and in addition, administrative and technical personnel competent in their respective duties.

d. There shall be a systematic record of diets, correlated with the medical records.

e. Departmental and interdepartmental conferences shall be held periodically.

2. *Medical Records Department*

a. Administrative Responsibilities

(1) There shall be a medical record maintained on every patient admitted for care in the hospital.

(2) Records shall be kept inviolate and preserved for a period of time not less than that determined by the Statute of Limitations in the respective state.

(3) Qualified personnel adequate to supervise and conduct the department shall be provided.

(4) A system of identification and filing to insure the rapid location of a patient's medical record shall be maintained. The unit number system is suggested; however, a serial number system or modification of this is acceptable.

(5) Records should be indexed according to disease, operation, and physician and should be kept up-to-date.

(6) All clinical information pertaining to a patient should be centralized in the patient's record.

(7) The Standard Nomenclature should be used as a nomenclature and is preferred if medical records are coded.

b. Medical Staff Responsibilities

(1) The medical record must contain sufficient information to justify the diagnosis and warrant the treatment and end results.

(2) Only physicians and members of the house staff are competent to write or dictate medical histories and physical examinations.

(3) Current records and those on discharged patients should be completed promptly.

(4) Records must be authenticated and signed by the physician.

c. The medical record should contain the following information:

(1) Identification data
(2) Complaint
(3) Present illness
(4) Past history
(5) Family history
(6) Physical examination
(7) Consultation
(8) Clinical laboratory reports
(9) X-ray reports
(10) Provisional diagnosis
(11) Tissue report
(12) Treatment: Medical and Surgical
(13) Progress notes
(14) Final diagnosis
(15) Summary
(16) Autopsy findings

3. *Pharmacy or Drug Room*

a. There shall be a pharmacy directed by a registered pharmacist or drug room under competent supervision.

b. Facilities shall be provided for the storage, safeguarding, preparation, and dispensing of drugs.

c. Personnel competent in their respective duties shall be provided in keeping with the size and activity of the department.

d. Records shall be kept of the transactions of the pharmacy, and correlated with other hospital records where indicated. Such special records shall be kept as are required by law.

e. Drugs dispensed shall meet the standards established by the United States Pharmacopeia, National Formulary, New and Non-official Remedies, British Pharmacopeia, or Canadian Formulary.

f. There should be an automatic stop order on dangerous drugs.

4. *Laboratories*

a. Clinical

(1) A clinical laboratory adequate for the individual hospital must be maintained in the hospital.

(2) Provision shall be made to carry out chemical, bacteriological, and serological examinations.

(3) Facilities should be available at all times.

(4) Personnel adequate to supervise and conduct the service should be provided.

(5) Urinalysis and at least a hemoglobin or hematocrit should be routine examinations on all admissions.

(6) Signed reports should be filed with the patient's record and duplicate copies kept in the department.

b. Pathological

(1) The services of a pathologist must be provided as indicated by the needs of the hospital.

(2) All tissues removed at operation should be sent for examination. The extent of the examination should be determined by the pathology department.

(3) Signed reports of tissue examination should be filed with the patient's record and duplicate copies kept in the department.

(4) Tissue reports should be indexed according to pathologic diagnosis.

c. Blood Bank

Facilities for procurement and safe-keeping of blood should be provided or readily available.

5. *Radiology*

a. The hospital must maintain radiological services according to the needs of the hospital.

b. The radiology department shall be free of hazards for patients and personnel.

c. The interpretation of radiological examinations shall be made by physicians competent in the field.

d. Signed reports should be filed with the patient's record and duplicate copies kept in the department.

e. Reports should be indexed according to radiological diagnosis.

6. *Medical Library*

a. The hospital must maintain a medical reference library according to the needs of the hospital.

b. Facilities should be provided to meet the requirements of the services in the hospital.

c. Basic textbooks and current periodicals should be available and catalogues according to the needs of the hospital.

d. Personnel should be provided to assure efficient service to the medical staff.

D. Services which may be maintained

1. *Medical Social Service Department.* If a department is maintained:

a. There shall be an organized department directed by a qualified medical social service worker, and integrated with other departments of the hospital.

b. Facilities shall be provided which are adequate for the personnel of the department, easily accessible to patients and to the medical staff, and which assure privacy for interviews.

c. Records of case work shall be kept. Such records shall be available only to the professional personnel concerned.

d. Departmental and interdepartmental conferences shall be held periodically.

2. *Emergency Service.* If a service is maintained:

a. There shall be a well organized department directed by qualified personnel and integrated with other departments of the hospital.

b. Facilities shall be provided to assure prompt diagnosis and emergency treatment.

c. There shall be adequate medical and nursing personnel available at all times.

d. Adequate medical records on every patient must be kept.

e. There shall be a written plan for the care of mass casualties and this plan should be coordinated with the in-patient and out-patient services of the hospital.

II. MEDICAL STAFF

A. Responsibilities

The governing body of the hospital must obviously delegate the responsibility of medical functions to the medical staff, including recommendations as to the professional qualifications of all who practice in the hospital. The medical staff is responsible for the quality of medical care rendered to patients in the hospital. Maintaining high standards of medical care will depend upon the character of the staff and the effectiveness of its organization to carry out the following duties:

1. Selection of those recommended for staff appointments and hospital privileges.
2. Constant analysis and review of the clinical work done in the hospital.
3. Support of medical staff and hospital policies.
4. Maintenance of adequate medical records.
5. Procurement of autopsies (a minimum of 20 to 25 per cent of hospital deaths).
6. Holding of necessary consultations. Except in emergency, consultation with another qualified physician shall be required in all first Caesarean sections and in all curettages or other procedures by which a known or suspected pregnancy may be interrupted. The same requirement shall apply to operations performed for the sole purpose of sterilization on both male and female patients. Included in consultations required under this Standard are all those which are required under the rules of the hospital staff. In major surgical cases in which the patient is not a good risk, and in all cases in which the diagnosis is obscure, or when there is doubt as to the best therapeutic measures to be utilized, consultation is appropriate. Obviously, judgment as to the serious nature of the illness and the question of doubt as to diagnosis and treatment rests with the physician responsible for the care of the patient. It is the duty of the hospital staff through its chiefs of service and Executive Committee to see that members of the staff do not fail in the matter of calling consultants as needed. A consultant must be well qualified to give an opinion in the field in which his opinion is sought. A satisfactory consultation includes examination of the patient and the record and a written opinion signed by the consultant which is made part of the record. When operative procedures are involved, the consultation note, except in emergency, shall be recorded prior to operation.

B. Membership

1. *Appointment*

a. Procedure

Staff appointments are made officially by the governing body. Recommendations are customarily made by the active staff, and in no case should a governing body make an appointment to the staff without such a recommendation.

b. Qualifications

Members of the staff must be qualified legally, professionally and ethically for the positions to which they are appointed.

c. Tenure

Limited terms of appointment are preferred but not required. The prevailing custom is for a term of one year, with reappointments continued as long as qualifications remain satisfactory.

2. *Categories*

The privileges of each member of the medical staff shall be determined on the basis of professional qualifications and demonstrated ability.

a. Active Staff

Regardless of any other categories having privileges in the hospital, there shall be an active staff, properly organized, which shall perform all the organizational duties pertaining to the medical staff. These shall include:

(1) Maintenance of the proper quality of all medical care and treatment in the hospital

(2) Organization of the medical staff, including adoption of rules and regulations for its government (which require the approval of the governing body), election of its officers, and recommendations to the governing body upon all appointments to the staff and grants of hospital privileges.

(3) Other recommendations to the governing body upon matters within the purview of the the medical staff.

b. Other Categories of the Staff

In larger hospitals, and in some smaller hospitals the medical staff may include one or more of the following categories in addition to the Active Staff but this in no wise modifies the duties and responsibilities of the Active Staff.

(1) Honorary Staff

The Honorary Staff shall be former active Staff, retired or emeritus, and other physicians of reputation whom it is desired to honor.

(2) Consulting Staff

The Consulting Staff shall be recognized specialists willing to serve in such capacity. A member of the Consulting Staff may also be a member of the Active Staff, but only if the two appointments are made.

(3) Associate Staff

The Associate Staff shall be those members who use the hospital infrequently or those less experienced members undergoing a period of probation before being considered for appointment to the Active Staff.

(4) Courtesy Staff

The Courtesy Staff shall be those who desire to attend patients in the hospital but who, for some reason not disqualifying, are ineligible for appointment in another category of the staff.

(5) Privileges of the Hospital
Privileges of the hospital may be extended to other qualified physicians under the same conditions as apply to the Courtesy Staff.

C. Organization

1. Officers

There shall be a President or Chief of Staff, a Vice President or Vice Chief, a Secretary, and such other officers as may be necessary for the government of the staff. These officers shall come from the Active Staff and shall be elected by the Active Staff, unless this is precluded by hospital organization.

2. Bylaws

Bylaws conforming to the principles expressed by the Joint Commission on Accreditation of Hospitals shall govern the staff.

3. Committees

The complexity of committee organization depends upon the size and composition of the medical staff of the individual hospital. A small staff may wish to function as a committee of the whole. Others may wish to combine committee functions in two or three committees. The structure of committee organization is a decision to be made by the medical staff so long as the following required committee functions are carried out:

a. Executive Committee
The Executive Committee shall co-ordinate the activities and general policies of the various departments, act for the staff as a whole under such limitations as may be imposed by the staff, and receive and act upon the reports of the Medical Records, Tissue and such other Committees as the medical staff may designate. The Executive Committee shall meet at least once a month and maintain a permanent record of its proceedings and actions.

b. Qualifications or Credentials Committee
The Qualifications or Credentials Committee shall review applications for appointment and reappointment to all categories of the staff. They shall delineate the privileges to be extended to the applicant and make appropriate recommendations to the staff.

c. Joint Conference Committee
The medical staff members of the Joint Conference Committee shall represent the staff in meetings with the governing body of the hospital or a committee of that body. This Committee shall be a medico-administrative liaison committee and the official point of contact among the medical staff, the governing body, and the administrator.

d. Medical Records Committee
The Medical Records Committee shall supervise and appraise the quality of medical records, and shall insure their maintenance at the required standard. The Committee shall meet at least once a month and submit to the Executive Committee a report in writing which will be made a part of the permanent record.

e. Tissue Committee
The Tissue Committee shall study and report to the staff, or to the Executive Committee of the staff, on the agreement or disagreement among the pre-operative, post-operative and pathological diagnoses and on whether the surgical procedures undertaken in the hospital were justified or not. This study will also include those procedures in which no tissue was removed. The report to the Executive Committee shall be in writing on at least a monthly basis.

4. Staff Meetings

The sole objective of staff meetings is improvement in the care and treatment of patients in the hospital. This is facilitated by a thorough review and analysis of the clinical work done in the hospital on at least a monthly basis.

a. There are three patterns for medical staff meetings which will accomplish this purpose:
   (1) Monthly meetings of the active staff, not less than twelve in each calendar year.
   (2) In well organized and departmentalized hospitals, departmental conferences and clinicopathologic conferences may be substituted for meetings of the entire staff, provided that an adequate review of the clinical work done in the hospital is covered by one or another of such conferences, and further provided that at least one meeting of the entire Active Staff is held during each quarter of the year. At such meetings a report of the review of the medical work of the hospital must be presented by the Executive Committee. In very large hospitals where attendance requirements are obviously met by departmental meetings and where physical facilities are not available for large audiences, the Commission may accept departmental meetings in lieu of meetings of the entire medical staff.
   (3) In hospitals where adequate review of the medical work in the hospital is carried out by the Medical Records and Tissue Committees, and appropriate study and action is taken by the Executive Committee on not less than a monthly basis, one meeting of the entire Active Staff must be held during each quarter of the year. At such meetings a report of the medical work of the hospital must be presented by the Executive Committee.

b. Active Staff attendance shall average at each meeting at least 75 per cent of the active staff who are not excused by the Executive Committee for just cause. Each active staff member shall attend 75 per cent of staff meetings unless excused by the Executive Committee for just cause.

c. In addition to matters of organization, the programs of such meetings must include a report of the Executive Committee and be limited largely to the review of current or recent cases in the hospital. Scientific programs not associated with the work of the hospital do not meet this requirement.

d. Business or other executive sessions of the staff shall be conducted by the Active Staff and other categories of the staff may be excluded.

e. Adequate minutes of all meetings shall be kept.

D. Departmentalization

Division of the staff into services or departments to fulfill medical staff responsibilities promotes efficiency and is recommended in general hospitals with 75 or more beds. Functional division of the medical staff into more than the minimal medical and surgical services is frequently desirable in larger hospitals. It is necessary that each autonomous service or department be organized and function as a unit. The following are considered minimal.

1. Personnel

Personnel of each service or department shall be qualified by training and demonstrated competence, and shall be granted priviliges commensurate with their individual abilities.

2. Chief of Service or Department

The chief of service or department shall be the member of the service or department best qualified by training and experience, and demonstrated ability for the position. He shall be responsible for the general character of the professional care of the patients on his service or department, and make recommendations as to qualifications of its members. His duties shall also include recommendation to the administrator as to the procurement of drugs, supplies, instruments, and equipment to insure maximum benefit to the patient. Additional duties of the chief of service or department shall include the following:

- a. Surgical—Recommendations as to sterile procedures and operating room policies.
- b. Obstetrical
  - (1) Supervision of care of newborn, if there is no organized service responsible for the nursery;
  - (2) Recommendations as to sterile procedures and delivery room policies.
- c. Clinical Laboratory
  - (1) Participation in staff and departmental meetings;
  - (2) Reporting upon all specimens examined, and maintaining a duplicate file of these reports in the department. This includes all tissues removed in the hospital.
- d. X-Ray Department
  - (1) Participation in staff and departmental meetings;
  - (2) Reporting upon all examinations and treatments, maintaining a duplicate file of these reports in the department,
  - (3) Insuring that safety precautions as to radiation and fire are observed strictly.

3. Conferences

Each service or department should have frequent, periodic conferences, attended by all its members, to consider clinical and organizational problems peculiar to the service. Records of these meetings shall be kept, become part of the records of the medical staff, and be available for inspection.

E. Departments which may be maintained

1. Anesthesia

The organization of the Department of Anesthesia shall be comparable to that of the other services of the medical staff. In addition, there shall be required in every case:

- a. Preanesthetic physical examination with findings recorded;
- b. Anesthetic record on special form,
- c. Postanesthetic follow-up, with findings recorded.

2. General Practice Department

A Department of General Practice shall be an organized segment of the medical staff comparable to that of other staff departments with the following modifications:

- a. The responsibilities of this department shall be limited to administration and education. It shall not be a clinical service and no patients shall be admitted to the department. If and when desirable, however, the department may be made responsible for conducting the outpatient clinic in whole or in part.
- b. Since the Department of General Practice will not have a separate service, the members of the General Practice Department shall have privileges in the clinical services of the other departments in accord with their experience and training, on recommendation of the Credentials Committee. In any service in which any general practitioner shall have privileges, he shall be subject to the rules of that service and subject to the jurisdiction of the chief of the clinical service involved.
- c. The medical staff should give to the General Practice Department such administrative responsibilities in the conduct of medical affairs as are desirable to meet the needs of the hospital.

3. Rehabilitation Department

The organization of the Rehabilitation Department shall be comparable to that of other departments of the hospital.

4. Outpatient Department

The Outpatient Department shall be organized into sections (clinics) the number of which shall depend on the degree of departmentalization of the medical staff, available facilities, and the needs of the community.

- a. Organization and Personnel
  There shall be such professional and non-professional personnel as are required for efficient operation.
- b. Facilities
  Facilities shall be provided to assure the efficient operation of the department.
- c. Medical Records
  Medical records shall be maintained, and correlated with other hospital medical records.
- d. Conferences
  Conferences, both departmental and interdepartmental, shall be conducted to maintain close liaison between the various sections within the department and with other hospital services.

5. Dental

The dental staff shall conform in general to standards established for the medical staff. In addition:

- a. Members of the dental staff must be qualified legally, professionally and ethically for the positions to which they are appointed.
- b. Patients admitted for dental services shall be admitted on a surgical service and shall be the responsibility of the chief of that service.
- c. Adequate medical survey by a member of the medical staff shall be done on each patient before dental surgery. Indicated consultations shall be held in complicated cases.

III. NURSING DEPARTMENT

Adequate care of the hospital patient requires well-organized and efficient nursing. All hospitals must meet the following requirements for accreditation:

A. Functions and Responsibilities

Nursing care for all patients is a primary responsibility of the nursing department, which must function in close relationship with other services of the hospital, both administrative and professional. This requires the establishment of a departmental plan of administrative authority with a definite outline of responsibilities and duties for each category of nursing personnel. This shall deal not only with patient care, but also with the educational responsibilities of the nursing department. Adequate nursing service must also be provided for the surgical suite, delivery rooms, clinics and other services of the hospital in keeping with the size and degree of activity.

B. Personnel

Personnel engaged for administrative or professional duties must be qualified by training and experience, and demonstrated ability for their assignments. All hospitals must provide nursing personnel to meet the following minimum requirements:

1. Director of Departments.
2. Assistant to the Director for evening and night services
3. Department or floor supervisors.
4. An adequate number of professional nurses and ancillary personnel for bedside care.

Nurses assigned to care for obstetrical patients and the newborn must not have other duties which may create danger of infection being carried to this service.

C. Records

Adequate records shall be maintained.

D. Departmental Meetings and Conferences

Meetings of the nursing staff, or of each department staff, shall be held at least monthly for discussion of nursing problems related to care of patients and administration.

Key Questions Considered by Committee

The Committee reviewed many facets of the problem of hospital accreditation. Following are a number of the key questions considered:

A. Should accreditation be continued? The Committee as well as all of those persons interviewed unequivocally are of the definite opinion that hospital accreditation should be continued.

B. Commission Membership: Although it might be advantageous to limit the membership of the Joint Commission to the Americal Medical Association alone or to the American Medical Association and the American Hospital Association, historic, legal, and other considerations have brought the Committee to the conclusion that it would be advisable to maintain the present representation. Admission of other organizations is a matter for the Joint Commission to consider, but the Committee believes the present representation is adequate. This Committee recommends that the American Medical Association representation always include at least one general practitioner, as has been customary in the past. The Committee also recommends that the other representatives of the American Medical Association continue to be rotated among the various specialties.

C. Activities of the Commission: (1) Should the Commission "punish" hospitals which discriminate against general practitioners? The Commission is not a punitive organization. It is set up ". . . to create in the hospital an environment which will assure the best possible care of the patient."

While the Commission has been blamed for some of the rejections of applications for staff appointments, it is the hospital board itself which approves or disapproves the appointment on the recommendation of the staff.

The Committee calls attention to the fact that in some areas staff appointments are based on board accreditation or member ship in specialty societies. The Committee strongly believes that these appointments should be based solely upon the physician's professional ability and ethical conduct without regard to his classification as a general practitioner or a specialist.

The Committee supports the stand of the Commission as published in section II-E-2 of the "Standards for Hospital Accreditation." This states, "A Department of General Practice shall be an organized segment of the medical staff comparable to that of other staff departments with the following modifications:

"a. The responsibilities of this department shall be limited to administration and education. It shall not be a clinical service and no patients shall be admitted to the department. If and when desirable, however, the department may be made responsible for conducting the outpatient clinic in whole or in part.

"b. Since the Department of General Practice will not have a separate service, the members of the General Practice Department shall have privileges in the clinical services of the other departments in accord with their experience and training, on recommendation of the Credentials Committee. In any service in which any general practitioner shall have privileges, he shall be subject to the rules of that service and subject to the jurisdiction of the chief of the clinical service involved.

"c. The medical staff should give to the General Practice Department such administrative responsibilities in the conduct of medical affairs as are desirable to meet the needs of the hospital."

The Committee again invites attention to the fact that appointments are made by the Board of the individual hospital on recommendation of the staff—not by the Joint Commission on Accreditation of Hospitals. It is the Board and staff which are responsible in each local situation.

(2) Is there a method of "appeal"? Yes, Article III, Section 8 of the bylaws states, "Hospitals which fail to receive initial accreditation or re-accreditation, or whose accreditation is revoked, shall, upon written request, be entitled to a hearing thereon before the Board of Commissioners or a subcommittee thereof designated by the Board for that purpose."

The Committee is of the opinion that there is misunderstanding by hospitals concerning procedure to be followed if acceditation is denied or withdrawn. If deficiencies admittedly exist and are the reason for denying or withdrawing accreditation, the hospital may request a re-survey when the deficiencies have been corrected. This is in no sense an appeal. If a hospital is denied accreditation, or it is withdrawn, and the hospital believes the reason for that action is not based on a proper survey or a proper evaluation of facts by the Joint Commission, it may ask the Commission to reconsider its actions. This is in the nature of an appeal and is provided for as noted in the above quotation.

When a hospital fails to receive accreditation, or accreditation is withdrawn, the Committee believes that the Joint Commission should simultaneously notify the administrator of the hospital and the chief of staff of the right to and the method of appeal of the decision.

(3) Should there be a final court of appeal higher than the Commission? The Committee has discussed the question of whether there can be an appeal to a body higher than the Joint Commission, but because of the organization of the Joint Commission, believes it is not feasible.

(4) Should the Commission report the results of a survey to the staff as well as the administrator? The Committee recommends that copies of the final report on the survey of the hospital which has been surveyed must be sent to both the administrator and the chief of staff of the hospital.

(5) Is the Joint Commission an autonomous body? Yes.

(6) Do the American Medication Association members on the Commission act as individuals or as representatives of the Association? They act as representatives of the American Medical Association. The Committee requests that the Board of Trustees of the American Medical Association include in its annual report to the House of Delegates a report on the activities of the Joint Commission.

D. Activities of Surveyors: (1) Should surveyors be employed entirely by the Commission? The present method of employing surveyors by each member organization promotes confused lines of authority, conflicting interests and loyalties, and administrative inefficiency; therefore the Committee recommends that the surveyors be employed by and be responsible to the Joint Commission. Attention is invited to the fact that the Joint Commission is not concerned with residencies and internship approval, which the American Medical Association will continue to survey.

(2) Should the surveyor have a joint meeting with staff or its representatives and the administrator after his survey? It should be mandatory that the field representative be accompanied by the administrator and a representative of the staff at the time of the survey. Further, he should meet with the administrator and the executive committee of the staff or its representatives following the survey for a review of the findings.

(3) Should new surveyors be better indoctrinated? The Committee believes that there should be closer liaison between the Joint Commission and its field representatives. They should be more adequately trained and immediately informed as to changes and interpretations in surveying procedures; they should be instructed to create excellent public relations understandings between the Commission, the profession, the hospital, and its personnel. Further, the surveyors should be indoctrinated with the ideas and ideals of the medical profession and the function of the hospital and its place in the community. The Committee believes that these objectives will be better accomplished when all surveyors are employed and supervised by the Joint Commission.

E. Staff Meetings and Attendance: Should the number of staff meetings and attendance be regulated by the Joint Commission? The Committee approves of the type and of the number of staff meetings laid down in the regulations of the Joint Commission, but it is of the opinion that compulsory attendance should not be required by the Commission but should be left to the discretion of the local staff.

F. Miscellaneous: (1) Should the American Medical Association accredit professional functions and the American Hospital Association administrative? After thorough study the Committee does not believe administrative and professional functions in accreditation can be separated but believes accreditation of the hospital should be done by the Joint Commission and accreditation of internship and residency programs should continue to be the function of the American Medical Association through its Council on Medical Education and Hospitals.

(2) Should there be physician representation on administrative bodies of the hospitals?

The Committee has reviewed the Report of the Joint Committee on Hospital-Psysician Relationships of the boards of trustees of the American Medical Association and American Hospital Association dated June, 1953. This statement suggests several methods by which the medical staff may have access to the hospital governing board including voting representation by members of the medical staff on the board. This Committee believes that it is desirable to have such staff representation on the governing bodies of hospitals and recommends that the Joint Commission encourage such representation. The Committee also urges medical staffs to request their boards of trustees to accept a medical member even if he serves only as a non-voting member.

(3) Should Blue Cross and other groups withhold payment from non-accredited hospitals until the Commission has had time to survey all hospitals? The Committee believes it should be made clear that any decision to pay claims or benefits, either in full or in part, depending on the accreditation of a hospital is an independent decision of Blue Cross and other groups. This decision cannot and should not be dictated or influenced by the Joint Commission.

The Committee is informed that the Joint Commission has not been able to inspect and accredit all hospitals seeking accreditation. It is reasonable to expect, however, that this will be accomplished in good time. The Committee is confident that Blue Cross and other groups will take into consideration the practical problems associated with the accreditation program so as not to work inequity on their subscribers.

(4) Should there be an educational campaign to acquaint the profession with the function rules and regulations of the Joint Commission on Accreditation of Hospitals? The Committee recommends that the American Medical Association conduct an educational program within the profession to inform its membership of the purposes of the Joint Commission.

The Committee recommends that each county medical society seriously consider devoting one meeting during the course of the year to a discussion of this particular problem and recommends that the state associations incorporate a symposium on this subject in their annual meeting programs.

(5) Should the Commission be concerned about the number of staffs to which any physician belongs? The Committee feels that staff membership in individual hospitals is a personal privilege and is of no concern to the Commission.

(6) Do the rules of the Commission discriminate against smaller hospitals? No, but it is recommended that the Commission give serious consideration to establishing standards which may vary depending upon the size of the hospital. Each hospital should be judged on its own merits and efficiency, regardless of size.

(7) Should a general practice section of a hospital be recognized? The Committee feels that the section on general practice in a hospital can never be clinical in nature because it is a part of the whole staff. However, as pointed out in Article V, Section 2 of the "Principles for Establishing Medical Staff By-Laws, Rules and Regulations—May, 1955," "A department of general practice may be organized. It is to be administrative and educational in function only. Patients admitted by members of this department will be admitted to the appropriate clinical department."

(8) Should the Joint Commission concern itself with questions of illegal or unethical contracts between hospital and physicians? Yes. The Commission in accomplishing its objective of assuring the best possible medical care of the patient must concern itself with every practice which prevents the patient from receiving the best possible care.

In the opinion of the Committee the existence of such practice must be determined at local level because the laws of the several states are not uniform. The effect of particular questioned practies should best be discussed by the field representative, the chief of staff, and the administrator at the joint meeting of these parties recommended in paragraph D. (2) above.

(9) Should the American Medical Association hold educational meetings to correlate the functions of the hospital Board of Trustees, the hospital administrator and the professional staff? Insofar as hospitals were established to provide the best possible care for the patient it is incumbent upon the American Medical Association to further these ideals at every opportunity. The Committee recommends that the American Medical Association hold annual national or regional educational meetings for this purpose.

Conclusions

1. Accreditation of hospitals should be continued.
2. The Joint Commission should maintain its present organizational representation.
3. The Board of Trustees should report annually to the House of Delegates on the activities of the Joint Commission.
4. Physicians should be on the administrative bodies of hospitals.
5. General practice sections in hospitals should be encouraged.
6. Staff meetings required by the Joint Commission are acceptable, but attendance requirements should be set up locally and not by the Commission.
7. The Joint Commission should not concern itself with the number of hospital staffs to which a physician may belong.
8. The Joint Commission is not and should not be punitive.
9. The Joint Commission should publicize the method of appeal to hospitals that fail to receive accreditation.

MEDICAL STAFF MEETINGS REQUIRED FOR ACCREDITATION

Choice	Meeting	When Held	Required Attendance *	Purpose and Program	Conditions
1.	Medical Staff	Monthly and not less than 12 meetings in each calender year	75 per cent of active staff	Review and critical evaluation of the clinical work in the hospital; report of committees	Suitable in smaller hospitals
2.	Staff Departments	Monthly or more frequently	75 per cent of active members of department	Review and critical evaluation of work of departments	May be substituted for (1) monthly staff meeting when hospital is well organized and all medical work is covered in departmental meetings and CPC's
	Medical Staff	Quarterly	75 per cent of active staff	Report of medical work for preceding quarter presented by representatives of departments or by executive committee	
3.	Medical Records & Tissue Committees or Audit Committee	Monthly or more frequently	75 per cent of members of committees	Review of all medical work in hospital, as stated in assignment of committee functions	May be substituted for (1) monthly staff or departmental meetings when hospital is well organized and all medical work is covered in committee conferences, and reports presented to staff
	Executive Committee	Monthly	75 per cent of members of committee	Appropriate study and action on reports of medical records and tissue committees or of Audit Committee	
	Medical Staff	Quarterly	75 per cent of active staff	Report of medical work for preceding quarter presented by executive committee to medical staff	

* Members may be excused by the executive committee for exceptional conditions such as sickness, absence from the community or medical emergencies.

10. Reports on surveys should be sent to both administrator and chief of staff of hospital.
11. Surveyors should be directly employed and supervised by the Joint Commission.
12. Surveyors should work with both administrator and staff.
13. New surveyors should receive better indoctrination.
14. Blue Cross and other associations should be requested not to suspend full benefits to non-accredited hospitals until those so requesting have been inspected.
15. The American Medical Association should conduct an educational campaign for doctors relative to the functions and operations of the Joint Commission.
16. The Committee also suggests that the Americal Medical Association and the American Hospital Association encourage educational meetings for hospital boards of trustees and administrators either on state or national levels to acquaint these bodies with the functions of accreditation.
17. This Committee asks to be discharged upon submission of this report to the House of Delegates.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. George S. Klump, Chairman, Pennsylvania, submitted the following report, which was adopted:

Report of Committee to Review the Functions of the Joint Commission on Accreditation of Hospitals.—Your reference committee received abundant advice regarding the general subject reported by the able Committee to Review the Functions of the Joint Commission on Accreditation of Hospitals, Dr. Wendell C. Stover, Chairman. It reviewed the content of the resolutions introduced at the 1955 Annual and Clinical Meetings, the two reference committees' reports related thereto, the Bylaws of the Commission, and two editions of the Standards for Hospital Accreditation published Dec. 5, 1953, and Jan. 28, 1956. Your committee believes that all of the questions raised in the 1955 resolutions have been answered adequately by this special committee, either directly or by obvious implication. Your reference committee notes with approval that the Speaker wisely selected several distinguished members of the House who had introduced these resolutions to serve on the study committee whose report is now before you.

The special committee outlines its procedures, the history of the Joint Commission and its structure. The current edition of the Standards for Hospital Accreditation is reprinted in the report. This material is informatory and requires no action. The special committee then notes certain key questions, together with some relevant discussion, and concludes with seventeen recommendations.

It was established at the outset of the hearing that the Standards for Hospital Accreditation are not a part of the special committee's report, except those sections quoted in the body of that report. Accordingly, your reference committee recommends that these Standards be included as an appendix in future publications.

Your reference committee has carefully considered all of the key questions considered by the special committee and its seventeen conclusions, both for a two hour period at the hearing and in the preparation of this report with the assistance of legal counsel.

Your reference committee agrees with Question A, that accreditation should be continued.

Your reference committee agrees with B, that the present representation on the Joint Commission is adequate.

In the course of the discussion a statement was submitted by Dr. John S. DeTar to be inserted after the third full paragraph under "C. Activities of the Commission." The special committee agreed that this statement, based on certain of the Standards for Hospital Accreditation would strengthen the report. These standards are II-B-2 and II-D-1. The statement follows:

The Committee recommends that the commissioners to the Joint Commission on Accreditation of Hospitals appointed by the Board of Trustees of the American Medical Association urge that Commission to study:

1. The problems of the exclusion from hospitals and arbitrary limitation of the hospital privileges of the general practitioner; and
2. Methods whereby the following stated principles may be achieved:

The privileges of each member of the medical staff shall be "determined on the basis of *professional qualifications* and demonstrated ability."

Personnel of each service or department shall be qualified by training and demonstrated competence, and shall be granted privileges commensurate with their individual abilities.

Your reference committee agrees with the addition of this statement to the special committee's report.

With this addition, the reference committee agrees with the comments of the Committee in section C.

The Committee makes several important suggestions in "D. Activities of Surveyors." The attention of the House is specifically directed to the method of employment of surveyors recommended, and to the fact that the American Medical Association will retain full responsibility for approval of internships and residency programs.

The reference committee heartily endorses the abolition of compulsory attendance at staff meetings, as recommended in section E.

The reference committee wishes to emphasize the importance of the recommendations in section F that there be medical staff representation on the governing boards of hospitals and that the Joint Commission concern itself with illegal or unethical contracts. These recommendations should lead to better understanding and clarification of the Standards as applied to hospital-physician relationships. Your reference committee believes that the other recommendations are eminently sound.

Your reference committee congratulates the members of the special committee for the painstaking work and great ability indicated by the clear and concise conclusions. It is the reference committee's opinion that further comment by it would be superfluous, for surely the conclusions speak for themselves. Your committee believes that the Committee to Review the Functions of the Joint Commission on Accreditation of Hospitals has performed a very difficult task superbly, that its conclusions are in the public interest, and that their implementation will result in the best possible medical care of the patient. In recommending the approval of the conclusions, your reference committee understands that it is also recommending the discharge of the Committee, and this should be done only with the sincere thanks of the House of Delegates.

Report of Continuing Committee on Medical Practices

Dr. Warde B. Allan, Chairman, presented the following interim report, which was referred to the Reference Committee on Insurance and Medical Service:

The House of Delegates in November, 1955, considered four resolutions: Resolution No. 11 on Creation of a Medical Practices Committee; Resolution No. 12 on Creation of Permanent Committee on Medical Practices; Resolution No. 20 on Report of Board of Trustees on Report of Committee on Medical Practices; and Resolution No. 28 on General Practice. These were introduced by Drs. Lester D. Bibler, Section on General Practice; Wendell C. Stover for the Indiana delegation; John S. DeTar for the Michigan delegation; and Kenneth C. Sawyer of Colorado, respectively. Since all of these resolutions dealt with the same subject, each emphasizing some special phase, the Reference Committee on Insurance and Medical Service submitted a substitute resolution, which was adopted by the House of Delegates. This substitute resolution created a Continuing Committee on Medical Practices consisting of five members of the House appointed by the Speaker, three of whom were to be general practitioners. The Speaker of the House has appointed this Committee, and two meetings have been held to undertake to plan the work of the Committee.

The resolution creating the Committee dealt primarily with general practice and with the relationship of medical and diagnostic services to surgical services, and much of the thought back of these resolutions came from the report of the Committee on Medical Practices presented to the House of Delegates in June, 1955. In view of this, the first task has been to review the report of the Committee on Medical Practices and to ascertain what might be the best approaches to the questions and the problems raised both in that report and in the resolution itself. In carrying out this step it is the intention of this Committee to interview all persons who may have a contribution to make and to seek advice from those who have a special interest in this subject.

As the Committee progresses in its work, reports on its findings and recommendations will be made to the House of Delegates in the same manner as is now followed by other committees and councils of the Association.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. John K. Glen, Chairman, Texas, read the following report, which was adopted:

Report of Continuing Committee on Medical Practices.—Your reference committee recommends the acceptance of this progress report for the information of the House.

Special Report of the Judicial Council

Dr. Homer L. Pearson, Chairman, presented the following report, during the reading of which the House of Delegates rose in tribute to Dr. Walter F. Donaldson. The report was referred to the Reference Committee on Amendments to the Constitution and Bylaws.

DR. CUNNIFFE

Since the Boston meeting of the House of Delegates, the members of the Judicial Council have been saddened at the news of the death of Dr. Edward R. Cunniffe, who retired as Chairman of the Council in June, 1954. Dr. Cunniffe was appointed a member of the Council in 1936 and was elected chairman in 1944. During these years he worked diligently and devotedly to fulfill the responsibilities of an office which he believed concerned medicine first and foremost. Convinced of the integrity and high moral character of the physician, he expected the highest regard for and observance of the Principles of Medical Ethics. He refused to recognize or accept efforts to carve exceptions to the Principles, which he conscientiously believed were binding on all who entered the profession of medicine.

He steadfastly maintained his beliefs during troubled times which included the period of recovery after a severe economic depression and the unsettled years of World War II. When the Association gave consideration in 1948 and 1949 to a revision of its Principles of Medical Ethics, Dr. Cunniffe was acknowledged to be the authority on medical ethics. He gladly accepted the obligations of his office and contributed his full share as a member of his profession and of this Association to maintain medicine's high ideals.

DR. DONALDSON

Since our arrival in Chicago, it has been called to our attention that Dr. Donaldson has asked to be allowed to retire from the Judicial Council after this session. The Council has received this news with regret.

Dr. Walter F. Donaldson, known and loved by all of us, has served medicine for many years in many capacities, not the least of which have been as editor of the *Pennsylvania Medical Journal* and as a member of this House of Delegates More important to us, however, has been his service to the American Medical Association, which has been without equal He was appointed to the Judicial Council in 1931 and has served continuously and faithfully in this office for 25 years. His contributions to the Association, both in length of time and in quality, are without precedent. More than an elder statesman, he has become a giant among us in matters pertaining to the Constitution, Bylaws, and Principles of Medical Ethics of the Association. Always informed and attentive, considerate and patient, possessed of mature judgment and wide experience in medical affairs, he became the keystone of the Judicial Council Admittedly, we cannot replace him, but we can emulate the example he leaves us. He has earned his place in the heart of this Association and he deserves a much needed rest.

The Association and the members of the Judicial Council in particular take this opportunity to express their love and respect to a truly great man for a lifetime of service.

PRINCIPLES OF MEDICAL ETHICS

Subsequent to the Boston meeting, the Judicial Council, as directed by the House of Delegates, met jointly with the Council on Constitution and Bylaws to consider a proposed revision of the Principles of Medical Ethics. Later, two members of each Council conferred to give further consideration to this matter. A draft of a proposed revision of the Principles was prepared which was submitted to the Judicial Council for consideration. This draft, a short form of the Principles, was accepted by the Judicial Council as representing an expression of principles which may be utilized by the physician in his sincere endeavor to serve his patient, the profession, and himself in accord with the high ideals of medicine.

From time immemorial, the Judicial Council in its reports to this House of Delegates has stated that the Principles of Medical Ethics are principles. The Council has repeatedly emphasized that they are, as their preamble clearly states, "intended to serve the physician as a guide to ethical conduct as he strives to accomplish his prime purpose of serving the common good and improving the health of mankind."

The Judicial Council would point out that in society, and in our organization as well, some conduct by its very nature is recognized as wrong, as contrary to the conscience of all. Other conduct, however, though not necessarily wrong in itself, may be proscribed to ensure safety, security, or well-being for the whole group. Murder is acknowledged to be wrong in itself. Driving on the left-hand side of the street is not wrong in itself but is contrary to law enacted to ensure safety by uniformity of conduct. Were the law by some wild stretch of the imagination to be amended to legalize murder, our conscience would revolt. Were the law to be changed to alter our pattern and custom of driving, from one side of the road to the other, our conscience would not thereby be affected.

Our Principles of Medical Ethics, if they are to be principles and if they are to be guides, must, in the opinion of the Judicial Council, relate to and concern themselves with fundamentals. They should express universal, permanent truths about which consciences do not disagree. They must be expressed with all the clarity that man can manage. The Principles of Ethics must avoid entering the realm of proscribing or permitting, by specific direction, acts which in themselves are not basically concerned with ethics or which are desirable or undesirable according to the social or economic circumstances of time, place, or custom.

As the Principles depart from fundamental ethical principles and encompass regulations to govern particular conduct, they become a code of laws. When the Principles become particular, it is inevitable that the nature of conduct is evaluated in relation to the Principles. Even today we are approaching that situation, and we hear it said that an act is not unethical because it is not prohibited by the *Principles of Medical Ethics* of the American Medical Association. A statement to that effect is incorrect. Conduct is ethical or unethical according to basic, unchanging principles. The Principles merely enunciate those basic, unchanging principles. The Principles of Medical Ethics, if they are worthy of the name, do not in themselves or of themselves make any act ethical or unethical. They announce a principle from which it may be reasoned that a particular act is ethical or from which a conclusion may be reached to determine the nature of a specific action.

The Judicial Council has maintained that ethical principles are founded in conscience, and the object of ethics is to know the rightness or wrongness of conduct according to conscience and reason. The principles upon which our ethics are based are permanent and universal. They are known, in conscience, to all honorable practitioners of medicine. The interpretation and application of these fundamental truths may vary, but the principles remain constant.

The Judicial Council hopes that the House of Delegates will see fit to adopt a revision of the Principles of Medical Ethics which includes only those fundamental concepts of ethics which guided our forebears and will be acknowledged by our successors; that the House will adopt a revision of the Principles of Medical Ethics which, in format, will be as permanent as the talents of this Association can make it.

The Judicial Council can and does endorse the revised draft of the Principles of Medical Ethics submitted by the Council on Constitution and Bylaws. Furthermore, the Judicial Council recognizes that if this proposal or one similar to it is adopted by the House, certain interpretations concerning its application will be desirable to insure the preservation of our ethical traditions. Should the new version be adopted, the Judicial Council is ready and pledges itself to prepare interpretations and annotations of ethical concepts in keeping with the tenor of our present code.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO THE CONSTITUTION AND BYLAWS

Dr. Jay J. Crane, Chairman, Section on Urology, submitted the following report, which was adopted:

Report of Judicial Council Relative to Dr. Donaldson and Dr. Cunniffe.—That portion of the report of the Judicial Council which pertains to the retirement of Dr. Walter F. Donaldson was read and was accepted with the same reluctance as expressed by members of the Judicial Council and all members of the House of Delegates.

Your reference committee read with deep sorrow the announcement of the death of Dr. Edward R. Cunniffe, the retired chairman of the Judicial Council, and approved of the tribute rendered to him in the special report of the Judicial Council.

Report of Council on Medical Education and Hospitals

The report of the Council on Medical Education and Hospitals (see THE JOURNAL, May 12, 1956, page 159) was presented by Dr. Victor Johnson, member of the Council, and was referred to the Reference Committee on Medical Education and Hospitals.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. George S. Klump, Chairman, Pennsylvania, read the following report, which was adopted:

Report of the Council on Medical Education and Hospitals.—Your reference committee has evaluated all of the statements presented at its hearing and has reviewed considerable material previously published relating to the Council's report, namely; the creation of a Cooperating Committee on Graduates of Foreign Medical Schools.

The Proceedings of the House of Delegates for the Annual Meeting in 1954 contains a supplementary report from the Board of Trustees, lettered O, which gives the conclusions of a special committee, chaired by Dr. Thomas P. Murdock, on this subject. Resolutions introduced at the 1954 session bearing on this matter were Nos. 27, 38, and 54, introduced by Drs. English, Foster, and Barker, respectively. A further discussion was presented at the Annual Congress on Medical Education and Licensure in 1955 and again this year. All of this material has been reviewed.

With this background in mind, your committee has studied the Council's present report thoroughly. Its primary objective is "to devise an effective mechanism for measuring educational attainment in the absence of intimate and continuing knowledge of the educational background of foreign-trained physicians." When implemented, this proposal will insure a proper level or standard for medical care everywhere in this country.

The program has been detailed under the general headings of: Basic Requirements; Examination for Factual Knowledge in Medicine; Administrative Planning.

Your committee agrees fully with both the details and the general views so well expressed in this report. Further, it is noted with satisfaction that the Board of Trustees has approved it in principle. The method of financing this program indicates that it may become self-supporting. Whether or not this proves to be true, your committee believes that a reasonable expenditure of the Association's funds is fully justified for this purpose.

This report culminates two and a half years of effort by the Council, indicating again its sincere desire to serve the public interest. It is to be commended for this detailed study and for its objective recommendations.

Your reference committee recommends that the House of Delegates approve in principle the program proposed in the report.

Report of the Council on Medical Service

Dr. Joseph D. McCarthy, Chairman, presented the following report of the Council on Medical Service, which was referred to the Reference Committee on Insurance and Medical Service:

Private Practice By Medical School Faculty Members

The Committee on Medical and Related Facilities, Dr. Willard A. Wright, Chairman, a committee of the Council on Medical Service, has been working during the past year on a study of private practice by medical school faculty members. This has not been an easy task. Difficult situations exist in some areas, bringing about adverse publicity as well as strong partisan reactions.

The Committee has received the finest cooperation from officers of state medical associations, local medical societies, and deans of the medical schools. It has also had assistance from an Advisory Committee, Dr. Henry B. Mulholland, Chairman, composed of representatives from the Council on Medical Education and Hospitals, the Association of American Medical Colleges, and the American Hospital Association.

The report of this Committee, as reviewed and revised by the Council on Medical Service, has been prepared in two sections for the convenience of the delegates. One section is concerned with the study or survey itself and provides a wealth of facts and opinions from medical association and medical society officers and medical school deans on private practice by medical school faculty members. This, the second section, is devoted to the conclusions and recommendations of the Council on Medical Service and its Committee on Medical and Related Facilities.

This is a long and detailed report, built upon a thorough study concerning a controversial subject which it is hoped will be resolved in the near future. In view of this, the Council would like, at this time, to submit the results of the detailed survey and the conclusions and recommendations to the House of Delegates for study during the coming months and for action at the 1956 Interim Session of the House.

This does not preclude discussion of the conclusions and recommendations by a House reference committee at this time. However, should this procedure be decided upon, the Council would respectfully suggest that such procedure be considered only preliminary and for the benefit of the American Medical Association and its component and constituent societies and associations. A time lapse should give all who are concerned with the problem an opportunity for a full review of their own particular situation before final action.

CONCLUSIONS AND RECOMMENDATIONS

In this survey it was found that to a varying degree controversy exists between medical schools and the physicians in private practice, as is alleged in the Culpepper resolution, and that, when the replies of the deans and the officers of the medical associations are considered and compared, there are differences of opinion as to the extent of this disagreement. This main controversy arises out of the question of the medical school or its full-time faculty entering into the private practice of medicine.

Historically, we find ourselves somewhat in the same position that we were in prior to 1913 at which time the concept of a full-time faculty was developed, primarily to improve the quality of medical education, but also to avoid conflicts between the local medical profession and the faculties of medical schools. However, presently the concept of the "absolute" full-time teacher is being modified because of economic and other pressures. As a result there are sharp differences of opinion on the matter of private practice between the local profession and the medical schools. These differences have been brought to the fore because of such factors as the establishment of new medical schools, the extension of medical school curricula from two to four years, and the construction of new medical school hospitals.

It is evident from all facts and data available to the Council that most, if not all, medical schools permit the so-called full-time faculty members to engage in private practice. In various areas, this has been a common procedure for many years, and while differences of opinion between the practicing physicians and the medical schools have arisen, many of these have apparently been mutually resolved.

Compensation of Teachers.—The Council is fully cognizant that many of the methods of compensating teachers of medicine leave much to be desired and some are to be condemned entirely because of the fact that the teachers may be exploited by the institutions they serve. Everything considered, the Council believes that some fundamental principles should be formulated in regard to these problems and accordingly presents the following conclusions and recommendations in the hope that they will assist medical societies and medical schools in developing programs which will be satisfactory to all concerned—the students, the teachers, and the practicing profession—so that in the end the public may receive the best possible medical care.

Definitions.—A great deal of confusion exists in regard to the present terminology used by medical schools to describe the status of their clinical faculty members. It is, therefore, recommended that the Council on Medical Education and Hospitals and the Association of American Medical Colleges adopt the following uniform definitions and that both take it upon themselves to urge all medical schools to adopt these definitions. Such action it is believed will make for better understanding and pave the way for amicable settlement of present conflicts and opinions.

The full-time faculty member is one who devotes all his time to the service of the medical school and receives all his professional compensation from a salary paid by the medical school.

Part-time faculty members receive a salary from the medical school; but they may be divided into two groups: (A) Physicians in the first group have medical school service as a major interest and usually conduct their private practice from facilities of the medical school. (This group includes many physicians called "absolute full-time" and most physicians called "geographical full-time" under present medical school terminology.); (B) Physicians in the second group have private practice as their major interest, utilize medical school facilities for teaching, and conduct their private practice from their own offices elsewhere.

A volunteer faculty member is a member of the faculty who receives no salary for his services to the medical school.

Liaison.—The Council has found that much of the present conflict in opinions has resulted from a failure in liaison between the practicing profession and the medical schools. In most instances of present conflict the profession and the schools worked hand in hand to build a good medical school and erect a teaching hospital. Yet, on completion of such joint endeavors all too frequently the initial spirit of cooperation and working liaison seems to have disappeared. In view of this it is recommended that adequate liaison be developed and maintained between each county medical society and any medical school or schools in its area and between each state medical association and any medical schools in the state. Such liaison should be the primary function of some committee of the state or county medical society, and methods should be developed so as to maintain communication between medical society committees within each state.

Medical society activity alone will not serve to maintain proper liaison. Accordingly, it is also recommended that the Council on Medical Education and Hospitals and the Association of American Medical Colleges urge all medical schools to assist and work with medical societies and associations in developing such liaison and urge them to confer with these committees whenever problems, questions, or policies arise that may concern private practice or in which the medical profession may be of assistance to the schools.

In this study it was evident that a large percentage of the medical school faculties is still in the part-time and volunteer categories. Complaints were made by deans that in some instances these men failed to fulfill their obligations to the school. Medical societies and associations complained that sufficient recognition was not given to these men for their services, mainly in the matter of policy determination. The Council recommends that when appointed, the services of volunteer and part-time men should be properly utilized and recognized by the medical school and these men should serve the school to the best of their ability.

It is further recommended that on request of a medical society or a medical school the American Medical Association's Board of Trustees establish, in cooperation with the Association of American Medical Colleges, a special committee whose function would be to investigate areas where there is friction between the medical school and the profession. Such a committee might (1) assure the continuation of liaison, (2) see to it that all data and facts are made available to all concerned and (3) seek to resolve differences of opinion.

Availability of Patients for Teaching Purposes.—It is evident to the Council that medical service and medical education have become quite complex. Economic factors, such as voluntary health insurance, extension of welfare benefits, increasing costs of hospitalization, etc., have created new facets to the problem of medical education, and especially have lessened the volume of indigent and medically indigent patients. Therefore, the Council recommends that all patients treated in medical school facilities be available for teaching purposes.

*Full-Time Faculty**.—It is evident from the information available to the Council that at the present time, in the opinion of both the medical schools and the medical societies replying to the questionnaire, income from private practice is necessary to attract and keep some portion of the clinical faculty. Our survey indicates that this seems to be more true in the case of private schools than in government schools.

It is the Council's belief that a nucleus of "full-time" clinical faculty members in the medical school is necessary. The Council believes that as a general rule the "full-time" clinical faculty members, as herein defined, should not be permitted private practice but should be paid an adequate salary by the medical school. Exceptions because of legal or local conditions may be necessary. The number and types of such "full-time" faculty members as are deemed necessary rest with each school, but in any event their salaries should be adequate and attractive enough to hold capable teachers.

*Part-Time Faculty**.—Over and beyond this nucleus of "full-time" faculty members every school has a large number of clinical teachers who are and should be classified as "part-time." These are so classified in the revised definitions recommended by the council and include many physicians now classified under medical school terminology as "absolute full-time" and most of those classified as "geographical full-time."

There seems to be no question concerning the privilege of private practice by "part-time" faculty members. There are, however, two basic questions to be kept in mind. The first is: What portion of the physician's time should be spent in teaching and what portion in private practice? The second question is: Where should the physician be permitted his private practice?

In regard to the first question, it is evident that even now all schools make some effort to limit private practice privileges as shown in the report on the survey itself. The extent to which these limitations are successful and to which they are actually providing a dividing line between teaching responsibility and private practice could not be accurately determined. However, the Council believes it is a primary responsibility of the administrators of medical schools to exercise adequate controls over the extent of private practice so as to maintain a proper relationship between teaching responsibilities and private practice.

The second question having to do with the place of practice seems to be the primary object of criticism in a number of areas, particularly in relation to government-supported schools. Here the teaching physician is accused of using tax-supported facilities to assist him in developing an income from private practice. The Council believes that all "part-time" faculty members should have the privilege of private practice. Such a privilege, however, should carry with it certain restrictions similar to those now utilized by most schools. As mentioned before, such restrictions should begin with a limitation as to the "amount of time" the physician may devote to private practice so as not to jeopardize the primary educational function of the medical school or of the individual teacher. The Council believes that charges should be made to the physician for all facilities and personnel involved in his private practice, pro-rated in accord with the use of such facilities in his private practice.

Publicity.—Considerable criticism has come to the attention of the council against local publicity given or sought by medical schools with reference to the work of individual staff members. We recommend that publicity emanating from a medical school should be in good taste and of a type which has the approval of the general medical community of that area.

Culpepper Resolution.—Finally, the Council would like to refer to the resolution introduced into the House of Delegates at the Interim Session in 1954 by Dr. J. P. Culpepper Jr., of Mississippi. The intent of this resolution would seem to be that the principle involved in a state-supported medical school using private practice as a source of funds for the general operation of a school or its hospital is contrary to medical ethics, and is, in effect, the corporate practice of medicine and state socialism. We recommend that it be the policy of the American Medical Association that funds received from the private practice of medicine by salaried members of the clinical faculty of the medical school or hospital should not accrue to the general budget of the institution and that the initial disposition of fees for medical service from paying patients should be under the direct control of the doctor or doctors rendering the service.

It is the firm policy of the American Medical Association, and in this policy the Council heartily concurs that only a licensed doctor of medicine should practice medicine. It is not in the public or professional interest for a third party to derive a profit from payment received for medical services, nor is it in the public or professional interest for a third party to intervene in the physician-patient relationship.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. John K. Glen, Chairman, Texas, submitted the following report, and moved its adoption. The motion was duly seconded. After lengthy discussion Dr. R. B. Robins, Arkansas, moved that the matter be re-referred to the reference committee, and the motion was seconded and carried.

Report of Council on Medical Service on Private Practice by Medical School Faculty Members.—Your reference committee sat for long in its hearing upon this report. It is, therefore, cognizant of the many difficulties inherent in the study of the subject and of the apparent impossibility of a happy solution for every portion of it. With certain changes the reference committee recommends the adoption of this report.

The recommended changes are as follows:

(1) Insert a period after the words, "House of Delegates," in the second sentence of the fourth paragraph of the report, and delete the remainder of that sentence.

(2) Delete the whole fifth paragraph of the report.

(3) Insert in the last sentence of the portion of the report under "Conclusions and Recommendations" bearing the sidehead, "Part-Time Faculty," after the phrase, "The Council believes that charges should be made," the words, "where possible under the existing laws of the state."

SUPPLEMENTARY REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. John K. Glen, Chairman, Texas, read the following supplementary report and moved its adoption. The motion was seconded, and carried after a substitute motion to postpone consideration of the report of the Council on Medical Service until the Clinical Meeting in November was lost.

Your reference committee, in accordance with the apparent wish of the House of Delegates to separate the question in regard to the report of the Council on Medical Service into a "supplementary report" of the Council and a Report on Private Practice by Medical School Faculty Members, has separated the question.

The "supplementary report" of the Council on Medical Service includes the first five paragraphs of the report presented on Monday, June 11. This portion of the report is now considered entirely alone as "supplementary report" of the Council on Medical Service, which "supplementary report" does pertain to the Council's report produced through the efforts of its Committee on Medical and Related Facilities, Dr. Willard A. Wright, Chairman.

Your reference committee agrees with this "supplementary report" except as it advises a delay, until the 1956 Clinical Meeting, in final action on the Report on Private Practice by Medical School Faculty Members.

Your committee therefore recommends the following changes in this "supplementary report":

---

*See recommended definitions above.

(1) Insert a period after the words, "House of Delegates," in the second sentence of the fourth paragraph of the report, and delete the remainder of that sentence.

(2) Delete the whole fifth paragraph of the report.

With these changes, your reference committee recommends the approval of this "supplementary report."

The Report on Private Practice by Medical School Faculty Members is the section mentioned in the third paragraph of the "supplementary report" as being concerned with the study or survey itself, plus the "Conclusions and Recommendations" in what was originally the report of the Council on Medical Service in our discussion of June 13, 1956.

Your reference committee recommends approval of this report in its entirety, with the single change as recommended previously. That change is as follows: Insert in the last sentence of the portion of the report under "Conclusions and Recommendations" bearing the side-head, "Part-Time Faculty," after the phrase, "The Council believes that charges should be made," the words, "where possible under the existing laws of the state."

The House of Delegates on June 13, 1956, approved an amendment to the report of your reference committee which provided for an addendum to the "Conclusions and Recommendations" in the form of a final paragraph, as follows:

"Nothing in this report is meant to condone the corporate practice of medicine or policies which result in the diversion of physicians' fees to a corporation or government agency."

Your reference committee believes it is the intent of the House that this addendum be included, and so recommends.

Report of Council on Constitution and Bylaws

Dr. Louis A. Buie, Chairman, presented the following report, which was referred to the Reference Committee on Amendments to the Constitution and Bylaws:

INTRODUCTION

This report deals with recommendations of the Council on Constitution and Bylaws and it consists of three parts.

1. SECTION ON PREVENTIVE MEDICINE

A resolution was introduced during the last session of the House of Delegates which read as follows:

> *Resolved*, That the Section on Preventive and Industrial Medicine and Public Health respectfully requests the House of Delegates of the American Medical Association to change the name of the Section on Preventive and Industrial Medicine and Public Health to the Section on Preventive Medicine.

This resolution was referred to the Reference Committee on Sections and Section Work, which recommended approval. The House adopted the recommendation of the reference committee, and requested the Council on Constitution and Bylaws to prepare appropriate alterations in the Bylaws which would implement the change. Therefore, the Council on Constitution and Bylaws recommend that the title, Preventive Medicine, be substituted for that of Preventive and Industrial Medicine and Public Health in Section 1(K) of Chapter VII of the Bylaws.

2. METHOD OF AMENDING PRINCIPLES OF MEDICAL ETHICS

In December of 1955 the Council on Constitution and Bylaws called to the attention of the House of Delegates the fact that neither the Principles of Medical Ethics nor the Constitution and Bylaws provide for amendment of the Principles, and that by custom amendments approved by a majority vote of the House of Delegates have long been recognized as valid. It was the opinion of the Council on Constitution and Bylaws that such changes should be made only after the most careful deliberation, and it therefore suggested that a section be added to the Principles which would provide for amending them. The Reference Committee on Miscellaneous Business recommended that this proposal be tabled for further consideration. The House of Delegates approved this action. The Council on Constitution and Bylaws has complied with the decision of the House of Delegates and now recommends that a provision for amending the Principles be incorporated in the Bylaws as follows:

Designate the present paragraph of Chapter XXI of the Bylaws, which provides for amendment of the Bylaws, as section 1, and add a second paragraph designated as Section 2, to read as follows:

"Section 2.—The Principles of Medical Ethics may be amended by the House of Delegates at any session on the approval of two-thirds of the members of the House of Delegates present and voting, provided that the proposed amendment shall have been introduced at the preceding session."

3. REVISION OF THE PRINCIPLES OF MEDICAL ETHICS

You will recall that in the past several committees have been engaged in revising the Principles of Medical Ethics. Also you are aware that this task was assigned to the Council on Constitution and Bylaws in June, 1952. For various reasons, discussed in former reports, it was not possible to make available to the House of Delegates an exhaustive analysis of the Principles until the December session of 1955. When that report was made, many of the complexities of this undertaking were revealed. For example, when the attempt was made to distinguish etiquette from ethics, it was readily apparent that a substantial portion of the Principles actually deals with matters in which morals, manners, and even economics are intermingled. In addition, some sections which are intended to deal with matters of courtesy might well be construed as involving problems of morality. At all events, it became clear, beyond doubt, that there exists a broad twilight zone in which the concepts of ethics and etiquette are entangled and in which there is much overlapping and consequent confusion.

An interesting point was noted with respect to Section 4 of Chapter VII, which provides a definition of free choice of physician. Once it has been read, the reader might assume that a preceding Principle proscribes activities which limit freedom of choice. Yet there is no such antecedent provision. Although the question of free choice of physician raises many problems that are involved in contract practice, workmen's compensation, prepaid health care, and other fields of insurance, the Principles do nothing more than define the term.

MEETING WITH THE JUDICIAL COUNCIL

The Council on Constitution and Bylaws has sought both counsel and criticism by means of publications in THE JOURNAL of the American Medical Association and by personal interviews and correspondence. Furthermore, in accordance with the request of the House of Delegates, a joint meeting with the Judicial Council was held on March 23, 1956. This meeting was attended by several ex officio members and by representatives of the Law Department. Those who attended this meeting reached the ineluctable conclusion that the present Principles are encumbered by verbosity and qualifying constructions of dubious value which in themselves engender confusion. Hence, it was felt that the Principles should be broad and should provide a framework within which interpretations could be made. They should deal with basic principles that can serve as a ready reference for the busy practitioner.

A subcommittee, consisting of the two chairmen of the respective councils and one other member of each council, was appointed to prepare a condensed version for consideration by both councils prior to the present session of the House of Delegates. During subsequent weeks several conferences were held, and on April 27 the subcommittee presented to the Judicial Council a new version of the Principles. During this meeting, after agreement was reached on some alterations, the members of the Judicial Council approved the proposed revision. Finally, on June 9, it was reviewed and approved by the Council on Constitution and Bylaws.

THE VIRTUES OF BREVITY

Doubtless the brevity of these Principles will attract your attention. If so, it is by design. All of us have become accustomed to a lengthy document. The Principles never have encompassed fewer than 40 sections, and in 1903, when the name was changed from Code of Medical Ethics to Principles of Medical Ethics of the American Medical Association, there were actually 53 sections. At present, the Principles are comprised of 48 sections. In the year 1846 the National Medical Convention, which was the progenitor of the American Medical Association, selected a committee charged with formulating a Code of Ethics. This committee, which submitted its report in 1847, patterned the principles which it proposed after those of Thomas Percival. Percival's principles contained 92 rules for the guidance of physicians, chiefly in their relationship with each other. His concept of ethics, which was published in 1803, can be held accountable for the volume and some of the content of the Principles which have served as our guide for more than a century.

On the other hand, there is nothing new or original about the quality of brevity in the present proposal. As examples, we have the Constitution of the United States, and, even more significant, the Ten Commandments. If further proof were necessary, we need only mention the Oath of Hippocrates, which in some 300 words (331 to be exact) outlines many of the basic principles on which most medical ethical codes have been built during the past 2,200 years. From the standpoint of integrity there has been no improvement over the principles enunciated in this oath, but from the standpoint of practical application, work has never ceased on the problem of adjusting them to the requirements of the contemporary scene.

PRACTICAL ECONOMY OF THE PROPOSED PRINCIPLES

The conclusions which are now offered for your consideration consist of a brief Preamble and 10 sections which succinctly express the fundamental ethical concepts embodied in the present Principles. Every basic principle has been preserved. On the other hand, as much as possible of the prolixity and ambiguity which in the past obstructed ready explanation, practical codification, and particular selection of basic concepts has been eliminated. The members of the Council believe and wish to emphasize that no fundamental ethical concept has been omitted from the Principles which are now presented for your consideration.

It is intended that this condensed version will provide the physician with a permanent yet readily accessible guide to ethical conduct which might be imprinted suitably on appropriate paper and displayed in the office of every member of the American Medical Association.

It will be supplemented by the opinions and interpretations of the Judicial Council, which are based on past decisions and pronouncements, and which are now being published in The Journal of the American Medical Association and are being collected and codified. No code of ethics could abbrogate this paramount function, and men of wisdom would not have it otherwise.

It is important to understand that medical ethics are not distinct or separate from ethics generally, but simply emphasize those general principles which are of particular concern to the medical profession. The ethical physician will observe all ethical principles, because he realizes that they cannot be enforced by penal reprisals but must be binding in conscience.

CONCLUSION

Each delegate has been provided with an annotated copy of the new Principles showing the manner in which they embody the Principles in use at this time. It is recommended that these proposed changes in the Principles be substituted for those submitted in December, 1955, and that they be sent to an appropriate reference committee, where ample opportunity can be provided for discussion of them by members of the American Medical Association. It is suggested that action by the House of Delegates be deferred until the November, 1956, session.

The Council on Constitution and Bylaws wishes to thank the members of the Judicial Council and Mr. C. Joseph Stetler and his associates of the staff of the Law Department for their invaluable assistance.

Principles of Medical Ethics of the American Medical Association

PREAMBLE

These principles are intended to serve physicians, individually or collectively, as a guide to ethical conduct. They are not laws; rather, they are standards by which a physician may determine the propriety of his own conduct. They are intended to aid physicians in their relationships with patients, with colleagues, with members of allied professions, and with the public to maintain under God, as they have through the ages, the highest moral standards.

Section 1. The prime objective of the medical profession is to render service to humanity with full respect for both the dignity of man and the rights of patients. Physicians must merit the confidence of those entrusted to their care, rendering to each a full measure of service and devotion.

Section 2. Physicians should strive to improve medical knowledge and skill, and should make available the benefits of their professional attainments.

Section 3. A physician should not base his practice on an exclusive dogma or a sectarian system, nor should he associate voluntarily with those who indulge in such practices.

Section 4. The medical profession must be safeguarded against members deficient in moral character and professional competence. Physicians should observe all laws, uphold the dignity and honor of the profession and accept its self-imposed disciplines. They should expose, without hesitation, illegal or unethical conduct of fellow members of the profession.

Section 5. Except in emergencies, a physician may choose whom he will serve. Having undertaken the care of a patient, the physician may not neglect him. Unless he has been discharged, he may discontinue his services only after having given adequate notice. He should not solicit patients.

Section 6. A physician should not dispose of his services under terms or conditions which will interfere with or impair the free and complete exercise of his independent medical judgment and skill or cause deterioration of the quality of medical care.

Section 7. In the practice of medicine a physician should limit the source of his professional income to medical services actually rendered by him to his patient.

Section 8. A physician should seek consultation in doubtful or difficult cases, upon request or when it appears that the quality of medical service may be enhanced thereby.

Section 9. Confidences entrusted to physicians or deficiencies observed in the disposition or character of patients during the course of medical attendance should not be revealed except as required by law or unless it becomes necessary in order to protect the health and welfare of the individual or the community.

Section 10. The responsibilities of the physician extend not only to the individual but also to society and demand his cooperation and participation in activities which have as their objective the improvement of the health and welfare of the individual and the community.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO THE CONSTITUTION AND BYLAWS

Dr. Jay J. Crane, Chairman, Section on Urology, presented the following report, which was adopted:

Report of Council on Constitution and Bylaws.—Your committee approves and recommends that the title, Preventive Medicine, be substituted for that of Preventive and Industrial Medicine and Public Health, in Section 1 (K) of Chapter VII of the Bylaws.

The second portion of the report of the Council pertains to the method of amending the Principles of Medical Ethics. The Council on Constitution and Bylaws recommends that the present paragraph of Chapter XXI, page 52 of the Bylaws, be designated as Section 1, and that a second paragraph designated as Section 2 be added, to read as follows: "The Principles of Medical Ethics may be amended by the House of Delegates at any session on the approval of two-thirds of the members of the House of Delegates present and voting, provided that the proposed amendment shall have been introduced at the preceding session." Your committee approves of this recommendation.

The third portion of the report refers to the revision of the Principles of Medical Ethics. Your committee approves of the revision of the Principles of Medical Ethics as prepared by the Council on Constitution and Bylaws and endorsed by the Judicial Council. After considerable discussion and the appearance of interested parties, your committee approves of the revision of the Principles of Medical Ethics presented, and although the committee feels that the new version of the Principles is ready for action at this time, it recommends that final action be deferred until the next regular session of the House of Delegates to allow ample opportunity for thorough study on the part of members of the American Medical Association.

(To be continued)

MEDICAL NEWS

CALIFORNIA

Course in Aviation Medicine.—The University of California at Los Angeles School of Medicine and University of California Extension will hold a special course in aviation medicine at the New Religious Conference Building, 900 Hilgard Ave., Los Angeles 24, Oct. 24-26. The staff will include Capt. Oran W. Chenault, M. C., U. S. Navy; Lieut. Col. John P. Stapp, M. C., U. S. Air Force, Holloman Air Force Base, N. Mex.; Capt. Ashton Graybiel, M. C., U. S. Navy, U. S. Naval School of Aviation Medicine, Pensacola, Fla.; Dr. Bruce V. Leamer, assistant professor of surgery, University of California at Los Angeles School of Medicine; and Dr. Aram Glorig, director of research, subcommittee on noise in industry of the committee on conservation of hearing of the American Academy of Ophthalmology and Otolaryngology in Los Angeles. The fee for the three-day sessions of six three-hour courses is $50. Requests for information concerning the course should be addressed to Dr. Thomas H. Steinberg, Assistant Dean for Postgraduate Medical Education, University of California Medical Center, Los Angeles 24.

Personal.—Dr. Edward R. Pinckney has resigned as health officer of Napa County and has accepted a position as Assistant Editor of The Journal of the American Medical Association. For the past two years he has been editor of the *Bulletin of the Napa County Medical Society*. He is being replaced by Dr. Sterling S. Cook, rear admiral, U. S. Navy, retired.

CONNECTICUT

Meeting of Medical Air Reserve.—The 9263rd Air Reserve Squadron, Medical Flight, will sponsor on Oct. 3 a scientific session (registration fee, $5) at Hugo's Restaurant, 715 Summer St., Stamford. Advance registration is desirable. The meeting will be held in conjunction with the semiannual meeting of the Fairfield County Medical Association, which is scheduled to convene the same evening at the Wee Burn Country Club in Darien. The scientific session will open at 9 a. m. with "Medical Management of Mitral Stenosis" by Dr. Frank D. Gray, New Haven. "Surgical Management of Mitral Stenosis" by Dr. J. Maxwell Chamberlain, New York, will precede a symposium by Dr. William H. Resnik of Stamford, Dr. Gray, Dr. Chamberlain, and Dr. Carl A. Jaeger, New Haven. The afternoon program will include "Medical Aspects of Massive Upper Gastrointestinal Bleeding" by Dr. Charles A. Flood, New York, "Surgical Aspects of Massive Upper Gastrointestinal Bleeding" by Dr. Louis M. Rousselot, New York, and a symposium by Dr. Flood, Dr. Rousselot, and Drs. C. Louis Fincke and Clayton B. Weed, Stamford. At the evening meeting of the Fairfield County Medical Association a social hour will precede the dinner, at which Brig. Gen. Harold H. Twitchell, surgeon, Continental Air Command, and director, Medical Reserve Training, will discuss "The Medical Air Reserve."

Course on Endocrinology.—Yale University School of Medicine will offer a postgraduate course for practicing physicians, "Endocrine Disease and Hormone Therapy," on Thursdays (2-5 p. m.), Oct. 11–Dec. 13 (no conference Nov. 22 and Dec. 6) in Farnam Auditorium, Yale–New Haven Medical Center, 789 Howard Ave., New Haven. The course is designed to provide internists and general physicians with a review of the commonly encountered endocrine disorders. No attempt will be made to cover the endocrinology of the gonads. There will be a question-and-answer period after each of the following programs:

Oct. 11, Control of Endocrine Secretion.
Oct. 18, Thyroid Deficiency—Myxedema, Cretinism, and Goiter.
Oct. 25, Hyperthyroidism.
Nov. 1, Adrenal Hyperfunction.
Nov. 8, Adrenal Insufficiency. Use of Adrenal Steroids in Clinical Medicine and Surgery.
Nov. 15, Pituitary Disorders.
Nov. 29, Parathyroid Glands and Disorders of Calcium Metabolism.
Dec. 13, Diabetes Insipidus. Spontaneous Hypoglycemia and Hyperinsulinism.

Dr. Philip K. Bondy, associate professor of medicine, Yale University School of Medicine, is the program director. Admission will be limited to those who have registered in advance. Registration fee and tuition will be $40 for the series of eight conferences. Interns and residents may register without charge. Inquiries should be addressed to the Assistant Dean, Postgraduate Medical Education, Yale University School of Medicine, 333 Cedar St., New Haven 11.

DISTRICT OF COLUMBIA

Award to Doctor Stubbs.—At the 30th annual alumni reunion of the George Washington University Medical Society, Dr. Donald H. Stubbs, assistant clinical professor of anesthesiology, George Washington University School of Medicine, Washington, D. C., was presented with an award of merit in recognition of his scientific and academic achievements and his services to the community. Dr. Stubbs, president of the medical service of the District of Columbia, is head of anesthesia and chairman of the executive and teaching staff of Doctors Hospital.

Miners Appoint Clinical Director.—Dr. Gordon M. Meade, chief of clinical services at the Williamson (W. Va.) Memorial Medical Center, has been appointed clinical director of the Miners Memorial Hospital Association, a chain of 10 hospitals serving beneficiaries of the United Mine Workers Welfare and Retirement Fund. During the last year Dr. Meade has served as clinical consultant with headquarters in Washington, D. C. He will succeed Dr. Aims C. McGuinness, who, after recruitment and organization of the hospital medical staffs, will return to private practice and teaching of pediatrics in Philadelphia. The newly opened hospitals were dedicated June 2 at Beckley, W. Va

GEORGIA

Personal.—Dr. R. Franklin Cary, health officer of the Macon-Bibb County Health Department, retired recently after 15 years of service as health officer. Dr. Cary, who reached the state's compulsory retirement age of 70 some months ago, was scheduled to retire March 1 but was persuaded by unanimous request of the state health department to continue in office until July 1.——Dr. D. S. Reese, Carrollton, a past president of the Carroll County Medical Association, which he served as secretary for more than 25 years, has been given the Founder's Day award of West Georgia College, Carrollton. Dr. Reese, who came to Carrollton in 1911, helped to organize the Carrollton Board of Health and the Carroll County Board of Health, which he served as chairman for many years.——Dr. William Gentry Thurman, a member of the house staff at Columbus City Hospital, was awarded a $1,000 cash prize at the recent meeting of the International Institute of Public Health, Maternal and Child Welfare Division of Canada, which offers a cash prize every 10 years to the Canadian medical student presenting the best scientific paper. During his senior year at the McGill University Faculty of Medicine, Montreal, Canada, Dr. Thurman entered a paper entitled "The Epidemiology of Diseases in Seaports"

ILLINOIS

Personal.—Col. Roland I. Pritikin, M. C., U. S. Army Reserve, Rockford, has returned from a lecture tour of hospitals and medical schools in Asia. Dr. Pritikin was the official delegate of the American Medical Association to the sixth Middle East Medical Assembly at the American University of Beirut, Beirut, Lebanon.——The Institute for Psychoanalysis, 664 N. Michigan Ave., Chicago, has added to its staff Dr. G. H. Pollock, associate professor of psychiatry, University of Illinois College of Medicine, Chicago, and Dr. Jay E. McCormick of Highland Park, who has served on the staff of Presbyterian Hospital of Chicago, as assistant clinical professor of psychiatry at the University of Illinois College of Medicine, and as consultant to the Institute for Juvenile Research.——Dr. Martin A. Seidell, Urbana, has won the 1956 Mississippi Valley Medical Society essay contest with his paper "A Compendium for Fluid and Electrolyte Management with Ordinary and Extraordinary Laboratory Facilities." On presentation of the paper at the annual meeting of the society at the Hotel Morrison, Chicago, Sept. 26-28, Dr. Seidell will receive a gold medal, a certificate, and a cash award.

Chicago

Bevan Lecture.—Dr. Richard B. Cattell of the Lahey Clinic, Boston, will deliver the 28th annual Arthur Dean Bevan Lecture before the Chicago Surgical Society at the Knickerbocker Hotel, 163 E. Walton, Oct. 5, 8 p. m. The subject of his address will be "Surgery of the Pancreas." The profession is invited.

Faculty Promotions.—The Chicago Medical School announces the promotion of Drs. Herman A. Jacobson and Lawrence S. Mann, associates in surgery, to clinical assistant professors of surgery; Dr. Caesar Portes, associate in proctology, to clinical assistant professor of proctology; and Dr. William A. Yacullo, associate in dermatology and syphilology, to clinical assistant professor of dermatology.

NEW JERSEY

Hospital News.—The Atlantic City Hospital will have as visiting chiefs pro tem Dr. Richard H. Lyons, chairman, department of medicine, State University of New York College of Medicine at Syracuse, Oct. 1-5; Dr. John H. Talbott, professor of medicine, University of Buffalo School of Medicine, Oct. 8-12; Dr. John J. Murphy, associate in urologic surgery, University of Pennsylvania School of Medicine, Philadelphia, Oct. 15-19; Dr. Jack D. Myers, chairman, department of medicine, University of Pittsburgh School of Medicine, Oct. 22-26; and Dr. Carroll S. Wright, professor of dermatology and syphilology, Temple University School of Medicine, Philadelphia, Oct. 29-Nov. 2.

NEW YORK

Lecture by Professor Kottmeier.—The Jewish Chronic Disease Hospital (East 49th Street and Rutland Road, Brooklyn) announces an informal talk on "Carcinoma of the Cervix," by Prof. Hans L. Kottmeier, chief of gynecology, Radium hemmet and Royal Caroline Institute, Stockholm, Sweden. Physicians are cordially invited to the meeting Oct. 2, 8:30 p. m. in the auditorium.

Pediatric Study in Mental Health.—Dr. Julius B. Richmond, chairman of pediatrics, State University of New York College of Medicine at Syracuse, has received a grant of $274,050 from the Ford Foundation for a five-year study of the early life relationships between mother and baby, from birth into the preschool years, and the implications of these relationships for development in later life. After his Air Force service in World War II, Dr. Richmond began these studies in Chicago, where he was assistant professor and then professor of pediatrics at the University of Illinois College of Medicine and superintendent of the Institute for Juvenile Research.

OHIO

Dr. Means Retires.—Dr. Russel G. Means, associate professor of otolaryngology at Ohio State University College of Medicine, Columbus, retired in June with the status of associate professor emeritus after 34 years on the faculty. Ill health prompted his resignation. Chairman of alumni activities for many years, Dr. Means is credited with sparking the drive for the present health center, and for this he was awarded the university's distinguished service award. In 1948 he received the College of Medicine Alumni Achievement award.

Course on Practical Physiology for Women.—An eight-week course on practical physiology for women opens for its sixth year this fall in the University of Cincinnati Evening College. Dr. Carroll J. Fairo, clinical instructor in surgery, gynecologic division, will conduct the series, the subject matter of which starts with the moment of conception and includes problems of puberty, menstruation, pregnancy, milk production, menopause, tumors, and malignant conditions. About 300 women have completed the course in previous years.

WASHINGTON

Dr. Churchill to Give Strauss Lecture.—On Oct. 19, Dr. Edward Delos Churchill, John Homans Professor of Surgery at Harvard Medical School, Boston, will give the seventh annual Alfred A. Strauss Lecture sponsored by the department of surgery of the University of Washington School of Medicine, Seattle. He will speak on "The Nature of Wounds and Wound Healing" at 8:15 p. m. in the auditorium of the Health Sciences Building, University of Washington campus. All physicians are welcome to attend the Strauss Lecture.

WISCONSIN

Social Guidance Conference.—The Four County Social Guidance Conference will meet Sept. 30-Oct. 1 at the Monterey Hotel, Janesville, to celebrate the 10th anniversary of the establishment of child guidance centers and mental health centers in Rock, Jefferson, Walworth, and Green counties. A celebration dinner will be held Sunday. Forums scheduled for Monday will bring together authorities in law, education, church and family life, medicine, and government to disseminate new technics and examine the work that has been done. Bruno Bettelheim, Ph.D., of Chicago will direct the forum on youth.

Circuit Teaching Programs.—The council on scientific work of the State Medical Society of Wisconsin, in cooperation with the state board of health, the medical schools of the University of Wisconsin and Marquette University, the Wisconsin Academy of General Practice, the Wisconsin Heart Association, the Wisconsin Anti-Tuberculosis Association, and the Wisconsin division of the American Cancer Society, has scheduled 12 circuit teaching programs. During October these clinics will be held at the Bellin Memorial Hospital, Green Bay, Oct. 9; St. Joseph-Lloyd Hospital, Menominee, Mich., Oct. 10; and St. Mary's Hospital, Wausau, Oct. 11. The faculty will consist of Drs. Gordon V. Marlow, Madison, proctology; Lamont R. Schweiger, Milwaukee, cardiology; Martin H. Seifert, Wilmette, Ill., internal medicine; and an obstetrician (to be selected). The registration fee, which includes a full afternoon and evening of instruction, with dinner, is $6. Physicians are requested to attend both sessions, as the meetings will be correlated, and those who attend both sessions will receive credit for Academy of General Practice membership requirements. Requests for reservations should be sent to the State Medical Society of Wisconsin, P. O. Box 1109, Madison.

GENERAL

Psychosomatic Society Invites Papers.—The American Psychosomatic Society, which will hold its 14th annual meeting at the Chalfonte-Haddon Hall in Atlantic City, N. J., May 4-5, 1957, invites the submission of titles and abstracts of 20-minute papers for consideration for the program. Abstracts, in sextuplicate, should be submitted no later than Dec. 1 to Dr. I. Arthur Mirsky, Chairman, Program Committee, at the society's headquarters, 551 Madison Ave., New York 22.

Meeting of Obstetricians and Gynecologists.—The Central Association of Obstetricians and Gynecologists will hold its 24th annual meeting at the Roosevelt Hotel, New Orleans, Oct. 4-6, under the presidency of Dr. Harold L. Gainey, Kansas City, Mo., who will deliver an address on Friday. The guest speaker, Dr. Clyde L. Randall, Buffalo, will discuss "Out of Sight—Not Out of Mind" at the close of the Thursday morning session. A cocktail hour, 6:30 p. m. Friday, will precede the annual banquet. In all, 15 presentations have been scheduled.

Essay Contest in Urology.—The American Urological Association offers annual awards totaling $1,000 (first prize, $500; second prize, $300; and third prize, $200) for essays on the result of some clinical or laboratory research in urology. Competition is limited to urologists who have been graduated not more than 10 years and to hospital interns and residents doing research work in urology. The first-prize essay will appear on the program of the meeting of the American Urological Association at the Hotel William Penn, Pittsburgh, May 6-9, 1957. Essays must be received before Dec. 1 by the executive secretary, Mr. William P. Didusch, 1120 N. Charles St., Baltimore.

Meeting on Prepaid Medical Service Plans.—The 12th annual Western Conference of Prepaid Medical Service Plans will convene at Sun Valley, Idaho, Oct. 10-14. The theme of the conference is "Are We Meeting the Challenge?" The key speakers will include Dr. David B. Allman, Atlantic City, N. J., President-

Elect of the American Medical Association; Dr. Charles A. Terhune, Burley, Idaho, president-elect of the Idaho State Medical Society; Odin W. Anderson, Ph.D., research director of the Health Information Foundation, and Dr. W. Palmer Dearing, deputy surgeon general of the U. S. Department of Health, Education, and Welfare, Washington, D. C. Other speakers from the fields of labor and industry will appear on the program.

Noise Abatement Symposium.—The seventh annual National Noise Abatement Symposium will be presented Oct. 11-12 at the Sherman Hotel, Chicago, under the joint sponsorship of the Armour Research Foundation of Illinois Institute of Technology, Acoustical Society of America, American Society of Safety Engineers, National Noise Abatement Council, American Society of Planning Officials, American Industrial Hygiene Association, and Acoustical Materials Association. The topics for discussion are "Quieting Machinery, the Noise Creator," "Hearing Loss Problems," and "Quieting a Noisy Environment." The registration fee, $15, covers the costs of the technical sessions, both luncheons, and a copy of *Noise Control Magazine* in which all papers presented at this meeting will be published. Address inquiries to: Armour Research Foundation of Illinois Institute of Technology, Attn.: Mr. Guy J. Sanders, 10 W. 35th St., Chicago 16.

Meeting of Medical Illustrators.—The 11th annual meeting of the Association of Medical Illustrators will be held Oct. 1-3 at the Iowa Center for Continuation Study, State University of Iowa, Iowa City, under the presidency of Mr. Leon Schlossberg, Baltimore. The central theme of the meeting will be "The Role of Visual Representation in the Acquisition and Transmission of Information," with special attention to its relationship to other means and uses for communication. Dr. Norman B. Nelson, dean of the State University of Iowa College of Medicine, will deliver an address of welcome at 9 a. m. Monday. "The Objective and Subjective Factors in Visual Perception" will be discussed at 10:45 a. m. by Dr. Herman M. Burian, Iowa City. The annual Max Brodell Memorial Lecture, "Criteria in the Judgment of Art," will be delivered by Mr. Lester D. Longman, head, department of art, at the annual banquet, 7:30 p. m. At 3:15 p. m. Tuesday Arthur H. Bulbulian, D.D.S., Rochester, Minn., will present "Advances in Materials and Methods Used in Preparation of Teaching Models and Facial Prosthesis." The annual exhibition of medical illustrations will be shown in the gallery of the University Fine Arts Building.

Southeastern Allergy Association.—The 11th annual meeting of the Southeastern Allergy Association at the Barringer Hotel, Charlotte, N. C., Oct. 5-6 will have as its theme "Allergy and Its Relationship to Medicine and Surgery." Dr. Ben N. Miller, Columbia, S. C., president, will serve as chairman for the Friday morning session, which will include the following papers:

Allergy and Its Relation to General Medicine, Emma K. B. MacInnis, Columbia, S. C.
Drug Allergy, David R. Thomas, Augusta, Ga.
The Steroids and Their Effect on Various Immunological and Allergic Reactions, Carl E. Arbesman, Buffalo, president, American Academy of Allergy.
Allergist, the Otolaryngologist, and the Patient, Theodore E. Walsh, St. Louis.
The Changing Picture of Allergy, Ethan A. Brown, Boston, president, American College of Allergists.
A New Look at Allergy, Charles P. Wofford, in collaboration with John B. McKinnon and Ben D. Hall, Johnson City, Tenn.

A clinical pathological conference at 2 p. m. will precede a panel on pediatric allergy. The banquet, 7:30 p. m., will follow cocktails (courtesy of G. D. Searle & Co.). The Saturday session will open at 9 a. m. with a panel, "Role of Chronic Lung Disease in Chronic Asthma," and will close with a question-and-answer period. This program has been accepted by the American Academy of General Practice for 10 hours of credit in category 2.

Low-Cost Medical Tours.—In conjunction with its seventh World Congress in London, July 22-26, 1957, the International Society for the Welfare of Cripples is organizing low-cost travel groups that, before and after the congress, will combine sightseeing with a survey of rehabilitation facilities. The group will leave New York by chartered plane for Glasgow, Scotland, July 13 and will go on a motor trip through the English Lake Country, visiting institutions in Glasgow, Edinburgh, and other communities along the way and arriving in London for the precongress social gathering July 21. Participants may choose between two travel groups leaving London after the congress on July 27: (1) to Oslo, Norway; Copenhagen, Denmark; Stockholm, Sweden; Brussels, Belgium; and Paris, France; and (2) to Zurich and Lucerne in Switzerland, then south into Italy to Venice, Ravenna, Florence, Perugia, Assisi, and Rome, and finally to Paris. These postcongress tours converge for a final two-day sojourn in Paris. The 59 members will fly back to New York on Aug. 10. The entire package, which includes a round-trip transatlantic flight and two study tours, is offered at a cost ranging between $908 and $960. Participants must be members of the U. S. Committee for the International Society for the Welfare of Cripples. Details on the tour and the congress may be obtained from the International Society for the Welfare of Cripples, 701 First Ave., New York 17.

Meeting of Rhinologic Society.—The American Rhinologic Society will hold its annual meeting in Chicago, Oct. 9-13, under the presidency of Dr. Ralph H. Riggs, Shreveport, La. A three-day series of surgical demonstrations and seminars will be presented in the Illinois Masonic Hospital from 8 a. m. to 10 p. m. under the direction of Dr. Maurice H. Cottle, professor and chairman of the department of otolaryngology, Chicago Medical School. The annual scientific program, presented in the Palmer House on the closing day, will include a morning symposium on "Expanding Horizons in Rhinology," with the following participants: Drs. Charles Petrillo, Yale University School of Medicine, New Haven, Conn. (anatomy); Newton D. Fischer, University of North Carolina School of Medicine, Chapel Hill (physiology); Harold S. Ulvestad, University of Minnesota Medical School, Minneapolis (surgery); and French K. Hansel, Washington University School of Medicine, St. Louis (allergy). Guest speakers on the afternoon program will be.

Roy R. Grinker, director of the Institute for Psychosomatic and Psychiatric Research, Michael Reese Hospital, Chicago, Psychosomatic Approach to Rhinological Problems.
Conrad L. Pirani, professor of pathology, University of Illinois College of Medicine, Chicago, Connective Tissue in Wound Healing
Hubert R. Catchpole, Ph.D., research associate professor of pathology, University of Illinois College of Medicine, Chicago, Newer Ideas on the Significance of Ground Substance of Connective Tissue.

Dr. Matthew S. Ersner, professor of otolaryngology and rhinology, Temple University School of Medicine, Philadelphia, will be the guest of honor and speaker at a dinner in the evening at which Dr. Riggs will serve as toastmaster. Physicians are welcome to attend the scientific session as guests of members of the society. There is no registration fee. Information may be obtained by writing to Mrs. Mabel Campbell, Corresponding Secretary, 834 Wellington Ave., Chicago 14.

American Dietetic Association.—The 39th annual meeting of the American Dietetic Association will be held in the Milwaukee Auditorium Oct. 9-12. At 3:30 p. m. Tuesday a program on diabetes and today's research will offer the following presentations:

An Approach to the Prediction of Diabetes Mellitus, Stefan S. Fajans, Ann Arbor, Mich.
Working with Children at the Joslin Camps, Alexander Marble, Boston
Treatment with New Oral Sulphonamide Compounds, Henry T. Ricketts, Chicago.

A discussion on nutrition in child health, Wednesday, 9:30 a. m., will include "Metabolism and Growth in Adolescence" by Dr. Joseph A. Johnston, Detroit. Wednesday evening will be devoted to a program at the Hotel Schroeder for discussion of "Nutrition Progresses." The opening paper, "Nutritional Deficiency Diseases Today," will be presented by Dr. William J. Darby, Nashville, Tenn. The following presentations by physicians are scheduled for Thursday:

Dietary Factors in Carcinogenesis, Wilhelm C. Hueper, Bethesda, Md
Medical Aspects of Aging, Frederick C. Swartz, Lansing, Mich
Proper Use of Modified Diets, Arnold L. Wagner, Evanston, Ill.
Low-Fat Diets in Cardiac Diseases, Peter T. Kuo, Philadelphia.
Dietary Constituents and Atherosclerosis, Theodore B. Van Itallie, Boston
Research Experience as a Part of Graduate Education, Charles F. Code, Rochester, Minn.
Nutrition in Liver Disease, Gordon M. Mindrum, Cincinnati.

At 9:45 a. m. Friday a session on "Today's Modified Diets" will include the following presentations:

Understanding and Support of the Patient, C. Knight Aldrich, Chicago
Rationale of the Bland Diet, Seymour J. Gray, Boston.
Chronic Sodium Chloride Toxicity and the Protective Effects of Potassium Chloride, George R. Heneely, Nashville, Tenn.

During the concluding session Friday afternoon, Dr. Charles F. Wilkinson, New York, will discuss "Obesity and Heart Disease," and Dr. Robert E. Olson, Pittsburgh, will have as his subject "Obesity Among Middle-Aged Men and Women."

Cancer Cytology Congress.—The International Cancer Cytology Congress will convene at the Drake Hotel, Chicago, Oct. 8-12 under the sponsorship of the American Society of Clinical Pathologists, College of American Pathologists, Inter-Society Cytology Council, and the International Union Against Cancer. The opening panel discussion on Hospital-Physician Relationships, Monday, 9:05 a. m., will be followed by an address by Dr. William A. D. Anderson, Miami, Fla., president of the College of American Pathologists. Other panel discussions will include:

Validity of Uterine Exfoliative Cytology, Cyrus C. Erickson, Memphis, Tenn., moderator.
Man-Power and Woman-Power, Recruitment and Training, Arthur T. Hertig, Boston, moderator.
Cancer Cytology Diagnostic Centers vs. Cancer Cytology Diagnosis at the Local Level, Joseph A. Cunningham, Birmingham, Ala., moderator.
Aspiration Biopsy, John T. Godwin, Atlanta, Ga., moderator.
Problems in Confirming Cellular Evidence of Cancer, Clyde L. Randall, Buffalo, moderator.
Prognosis in Cancer of the Uterine Cervix as Determined by Histologic and Cytologic Methods, John B. Graham, Boston, moderator.

Thursday morning will be devoted to papers on advances in cytology and Thursday afternoon to a symposium, "Carcinoma in Situ of the Uterine Cervix," moderated by Dr. Arthur T. Hertig, Boston. An all-day tumor seminar on breast lesions, to be presented Friday by the American Society of Clinical Pathologists, will be conducted by Dr. Lauren V. Ackerman, St. Louis. Saturday and Sunday will be devoted to workshops and refresher courses. The joint banquet, Tuesday, 7 p. m., will be preceded by a reception. A roundtable luncheon is scheduled for Wednesday, 12:15 p. m., and fellowship hours for 6 p. m. on Monday and Wednesday, preceding the annual meetings respectively of the College of American Pathologists and the Inter-Society Cytology Council. The American Society of Clinical Pathologists will hold its annual meeting Thursday, 8 p. m.

Meeting on Surgery of Trauma.—The American Association for the Surgery of Trauma will hold its 16th annual session Oct. 4-6 at The Biltmore, Santa Barbara, Calif., under the presidency of Dr. Warren H. Cole, Chicago. The presidential address Friday will be preceded by a symposium entitled "Trauma Incident to High-Speed and High-Altitude Flying," which will be moderated by Major Gen. Dan C. Ogle, M. C., U. S. Air Force. Other participants from the U. S. Air Force Medical Corps will include Lieut. Col. John P. Stapp, Holloman Air Force Base, N. Mex.; Lieut. Col. Andres I. Karstens, Randolph Air Force Base, Texas; Col. Robert B. Lewis, New York; Capt. Clyde H. Kratochvil, Randolph Air Force Base, Texas; Capt. Robert T. P. deTreville, Wright-Patterson Air Force Base, Ohio; Col. Harry G. Moseley, San Bernardino, Calif.; and Col. Arthur M. Henderson, Medical Service Corps, retired, Santa Monica, Calif. The program of 37 papers includes 38 invited participants. A cocktail hour at 7 p. m. Friday will precede the banquet (black tie preferred), at which Lieutenant Colonel Stapp will present "Crash Protection in Automobiles." Ladies and guests are invited to the annual dinner.

FOREIGN

Symposium on Allergic Diseases.—A symposium on allergic diseases will be held at l'Hôpital Broussais, 96, rue Didot, Paris XIV^{e}, France, Oct. 15-25. The cost of the course is 5,000 francs (about $14.50) for the lectures and 10,000 francs for both lecture course and practical demonstrations. Applications should be sent, and checks made out, to the Clinique Médicale Propédeutique de l'Hôpital Broussais. The number of enrollments is limited. The 37 presentations will include 16 by Prof. Pasteur Vallery-Radot and 9 by Dr. B. N. Halpern, both of Paris.

Meeting on Hydatid Disease.—The International Association of Hydatidology held its sixth congress at Athens, Greece, Sept. 14–18, under the sponsorship of King Paul I, with the cooperation and subsidy of the Greek government and UNESCO. Reports were made on "Occupational Hydatidosis," "The Rupture of Hydatic Cysts of the Liver in the Bile Ducts," "The Rupture of Hydatic Cysts of the Liver, Lung, and Bronchi, Present State of Surgical Treatment," and "Hydatidosis from the Socioeconomic Point of View."

CORRECTION

Report on Medical Education.—The totals in table 26 in the 56th Annual Report on Medical Education in the United States and Canada, in The Journal, Aug. 25, page 1661, should read "Total Applications." While the figures in columns 2, 3, and 4 represent the number of applicants for each school, the totals of the columns can represent only the total number of applications. Thus, while the total applications for 1955-1956 increased 14% over the preceding year, the total number of applicants increased only 3%.

EXAMINATIONS AND LICENSURE

American Board of Anesthesiology: *Part I.* Various locations, July 19. Final date for filing application is Jan. 19. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Dermatology: *Oral.* St. Louis, Oct. 12-15. Final date for filing applications was April 1. Sec., Dr. B. M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *Written.* Oct. 15, 1956. Final date for filing application was May 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.
Subspecialties. Cardiovascular Disease. Chicago, Nov. 30. Final date for filing application was June 1. *Gastroenterology.* Philadelphia, April 5-6. Final date for filing application is March 1.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Part I.* Various cities of the United States, Canada, and military centers outside the Continental United States, Feb. 1. Candidates must submit case reports to the office of the Secretary within thirty days of being notified of their eligibility to Part I. *Part II.* Chicago, May 16-25. Request for reexamination in Part II must be received prior to Feb. 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology: *Oral.* St. Louis, Oct. 20-24. *Written.* Jan. 21. Final date for filing application was July 1. *Oral.* New York, May 23-27; Chicago, Oct. 7-11. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral. Part II.* Chicago, January 1957. Final date for filing application was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Written and Oral.* Chicago, Oct. 8-11. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: *Written for Pathological Anatomy and Clinical Pathology,* Oct. 4-6. Final date for filing application was Sept. 1. Sec., Dr. Edward B. Smith, 1040-1232 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Oral. Part II.* New York City, Oct. 12-14, and San Francisco, Dec. 7-9. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Parts I and II.* New York City, June 8-9. Final date for filing application is March 1. Sec., Dr. Earl C. Elkins, 200 First St., S.W., Rochester, Minn.

American Board of Plastic Surgery: Miami, Oct. 17-19. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *Oral and Written. Public Health.* Philadelphia, Nov. 8-10. Sec., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore, Md.

American Board of Psychiatry and Neurology: *Oral.* New York, Dec. 10-11 and New Orleans, Mar. 18-19. Final date for filing application is Sept. 10. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: Los Angeles, Sept. 30-Oct. 4. Final date for filing application was June 1. Tampa, April 1-6. Final date for filing application is Jan. 1. Washington, Sept. 23-28. Final date for filing application was June 1. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Various centers throughout the United States and in certain military centers abroad, Oct. 31. *Part II.* Rochester, Minnesota, Oct. 15-16; New Haven, Nov. 19-20; Kansas City, Kan., Dec. 10-11; Los Angeles, Jan. 14-15; San Francisco, Jan. 17-18; Houston, Feb. 18-19; Nashville, Mar. 11-12; Boston, April 8-9, and New York, June 10-11.

American Board of Urology: February 1957. Sec., Dr. William Niles Wishard, 1711 N. Capital Ave., Indianapolis 7.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, February 1957, and the closing date for registration is Dec. 1, 1956. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

GOVERNMENT SERVICES

NAVY

Naval Summer Training for Medical Students.—One hundred eighty-two ensigns (medical) are participating in summer cruises at 16 naval teaching hospitals and nine naval medical research activities. These trainees are students in medical schools during the regular school term and during the summer months are participating in the 60-day clinical clerkship and research clerkship training that is a part of the Navy's ensign (medical) program. In addition to receiving the full pay and allowances of their rank, these officers receive excellent on-the-job training commensurate with their professional attainments while serving at either a naval hospital or naval medical research activity. These programs begin July 1 of each year and end June 30 of the subsequent year.

Exhibit at Air Show.—Representing the Bureau of Medicine and Surgery, Commander Carl E. Wilbur, M. C., presented an exhibit at the National Air Show in Oklahoma City, Sept. 1-3, 1956. This presentation featured the latest developments in Navy aviation, clothing, and personnel equipment. The following items were displayed: static vibrating and pulsating back and seat pads, mine safety flight helmet, antiexposure suits, oxygen breathing equipment, and summer-winter flight suits and two-piece suits. The Air Crew Equipment Laboratory, U. S. Naval Air Material Center, Philadelphia, loaned material for the exhibit. Chief Parachute Rigger William H. Hanggeli, from the Material Center, assisted in assembling and monitoring the exhibit.

Fourth Naval District Symposium.—The seventh Annual Military Medico-Dental Symposium under the auspices of the Commandant, Fourth Naval District, will be held at the U. S. Naval Hospital, Philadelphia, Oct. 22-27, 1956. The theme of the symposium is "The Medical Aspects of Hemispherical Defense," and the program has been planned to provide reserve and regular medical department officers with information regarding current concepts in varied fields of endeavor in the medical and dental services of the armed forces.

PUBLIC HEALTH SERVICE

The New Health Research Facilities Act.—The President has signed the Health Research Facilities Act of 1956, which authorizes the appropriation of funds to assist in financing the construction of facilities for research in the sciences related to health, which the act defines as including medicine, osteopathy, dentistry, and public health and fundamental and applied sciences when related thereto. The assistance is to be in the form of grants-in-aid to public and nonprofit institutions on a basis of not more than 50% for the federal share. Items not creditable for matching purposes include (1) costs for the acquisition of land or off-side improvements and (2) obligations made prior to the award of the research facilities grant concerned. Congress has now appropriated 30 million dollars to the Public Health Service, Department of Health, Education, and Welfare, for this program.

The funds are to be used to provide additional research facilities through the construction and/or equipping of new buildings or the expansion, remodeling, alteration, and/or equipping of existing buildings. The new law provides for the appointment of a national advisory council on health research facilities, which is expected to meet in the near future to establish policies and approve regulations for the administration of the new program. The surgeon general is not permitted to award a research facilities grant-in-aid that has not previously been approved by the council. Additional information will be supplied on request to the Division of Research Grants, National Institutes of Health, Public Health Service, Bethesda 14, Md.

Summer Students.—Seventy-seven medical and dental students from 23 approved four-year professional schools are spending the summer months at hospitals, research laboratories, and other facilities of the U. S. Public Health Service participating in an annual summer student training program. Assignments under this program are open each year to students who complete either their second or third year of professional education on or before July 1 and who are interested in becoming reserve officers in the service's commissioned corps.

Students who are selected for employment are offered commissions as reserve officers in grades equivalent to those held by officers in the armed services. They are then placed on active duty for a period not to exceed 120 days. Opportunities for either internship or active duty on completion of intern training are made available to qualified students.

The service said the purpose of the summer employment program is (1) to stimulate the interest of promising students in careers in the Public Health Service; (2) to enable students to further their professional knowledge while being gainfully employed; (3) to give students an opportunity to increase their understanding of and interest in the functions of government and independent public health agencies; and (4) to provide the service with competent help during the summer months.

New Water Pollution Act.—Preliminary information on the operation of the new Federal Water Pollution Act has been released by Surgeon General Leroy E. Burney. Among other things, the new law authorizes federal grants to municipalities to assist in the construction of sewage treatment works as a pollution control and water conservation measure. The act also authorizes a five-year program of grants to states and to interstate water pollution control agencies to assist in developing their own pollution control operations. A revised federal enforcement procedure for control of interstate pollution and greater federal support of water pollution research are among other important provisions of the act.

Secretary Marion B. Folsom of the Department of Health, Education, and Welfare has written the governors of all states and territories calling attention to the seriousness of the water pollution problem and requesting their active cooperation in carrying out the cooperative state-federal provisions of the new legislation during the current fiscal year.

Reserve Officers Appointed.—The U. S. Public Health Service announced on Aug. 26 the appointment of 98 physicians, nurses, sanitary engineers, and pharmacists to the inactive reserve component of its commissioned officer corps. These officers are among the specialists to be appointed under the service's program to organize and train health and medical personnel throughout the United States and its territories for emergency duty in times of national crisis. These officers will serve in the capacities for which their professional training and experience have fitted them. They will be called out principally to reinforce the staffs of official state and local health agencies and to augment the Public Health Service operating staff.

Training in Neurological Diseases.—The National Institute of Neurological Diseases and Blindness announces that funds are being made available to medical schools to strengthen clinical programs in advanced training in the neurological diseases The purpose is to stimulate the interest of young physicians and scientists in careers as teachers and investigators. Training grants also are available to basic science departments to expand postdoctoral training programs in the neurological sciences. Information, together with application forms, may be obtained from the Chief, Extramural Programs, National Institute of Neurological Diseases and Blindness, National Institutes of Health, Bethesda 14, Md.

Dr. Bauer Appointed Deputy Chief.—Dr. Theodore J. Bauer, for the past three years chief of the Communicable Disease Center in Atlanta, Ga., has been named deputy chief of the Bureau of State Services, replacing Dr. Leroy E. Burney, who was recently appointed surgeon general. Dr. Bauer was venereal disease control officer for the Chicago Board of Health from 1942 to 1945 and chief of the venereal disease division of the Public Health Service in Washington from 1948 to 1953.

DEATHS

Bryant, William Sohier, New York City; born in Boston May 15, 1861; Harvard Medical School, Boston, 1888; secretary, Section on Laryngology and Otology from 1905 to 1908, when he became Chairman, serving until 1909, and in 1912 member of the House of Delegates of the American Medical Association, of which he was an associate member; member of the American Laryngological, Rhinological and Otological Society, Boylston Medical Society, Boston Medical Library Association, Association of Military Surgeons of the United States, and the American Otological Society; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; veteran of the Spanish-American War; during World War I was with the British forces as contract surgeon in charge of the Royal Victoria Hospital, London, England, and otolaryngologist for the British Red Cross Hospital at Netley, England; later served also with the French forces, and finally with the American Red Cross Military Hospital in Paris, France, and with the American Red Cross in Italy; retired as a colonel in the Officers Reserve Corps; began practice in Boston, where he was aural surgeon at the Boston Dispensary, assistant in anatomy and otology at Harvard Medical School, and senior assistant surgeon at the Massachusetts Eye and Ear Infirmary; formerly on the faculty of Columbia University College of Physicians and Surgeons, Cornell University Medical College, and the New York University Post-Graduate Medical School and Hospital; served on the staffs of the New York Eye and Ear Infirmary, the Presbyterian Hospital, and the Manhattan State Hospital; held the French Legion of Honor, Order of the Crown of Italy, and Grand Cross of the Order of St. John the Baptist; awarded the Grand Cross Order of St. John of Jerusalem; belonged to many American patriotic groups, including the Society of Mayflower descendants and the Sons of the Revolution; author of many articles pertaining to his field; died in the Mount Auburn Hospital, Cambridge, Mass., June 26, aged 95, of injuries received in an automobile accident.

Austrian, Charles Robert ⊕ Baltimore; born in Baltimore May 28, 1885; Johns Hopkins University School of Medicine, Baltimore, 1909; since 1950 associate professor emeritus of medicine at his alma mater, where he was assistant instructor and associate in medicine from 1910 to 1923, when he became associate professor of medicine; past-president of the Johns Hopkins Medical Society, Baltimore City Medical Society, and the Medical and Chirurgical Faculty of Maryland, of which he was formerly councilor; member of the Association of American Physicians, American Society for Clinical Investigation, American Trudeau Society, American Clinical and Climatological Association, Southern Medical Association, and the American Association of Pathologists and Bacteriologists; specialist certified by the American Board of Internal Medicine; medical advisor to the state director of the Selective Service System and during World War II served on the Civilian Mobilization Committee; physician-in-chief at the Sinai Hospital from 1921 to 1944 and since 1947 chief medical consultant; member of the staff of the Union Memorial Hospital and the Hospital for Women; since 1915 visiting physician at the Johns Hopkins Hospital, where he was formerly chairman of the medical advisory board; at one time a member of the state board of welfare; past-president and member of the board of trustees of the Park School; in 1935 was presented with the gold medal of the Phi Lambda Kappa medical fraternity, the medal awarded annually to the "Jewish physician considered as having contributed most to medical science in the preceding year"; served as a member of the board of trustees, Peabody Conservatory of Music and the Baltimore Symphony Orchestra; on the editorial board, *Bulletin of Johns Hopkins Hospital;* died July 13, aged 71, of coronary thrombosis.

Loeb, Virgil ⊕ St. Louis; born in Columbia, Mo., Feb. 28, 1883; St. Louis University School of Medicine, 1906; also a dentist; professor emeritus of pathology at Washington University School of Medicine, where he was lecturer on stomatology; professor of oral surgery at St. Louis University from 1907 to 1919; professor of stomatology at the Washington University Dental School from 1921 to 1934; fellow of the International College of Dentists, American Academy of Periodontology, and the American Association for the Advancement of Science; chairman, Section on Stomatology of the American Medical Association, 1912-1913; past-president of the St. Louis Dental Society and the Missouri Dental Association; member of the American Public Health Association, American Society for Dentistry for Children, Federation Dentaire Internationale, Phi Beta Pi, Delta Sigma Delta, Omicron Kappa Upsilon, and Pi Gamma Mu; during World War I was a major in the Medical Corps of the U. S. Army and a consultant in facial surgery at Mesves Hospital Center in France; member of the staffs of the Evangelical Deaconess, St. Louis Maternity, St. Louis Children's, and Jewish hospitals; died June 26, aged 73.

Medlar, Edgar Matthias, Tupper Lake, N. Y.; born in Ohiowa, Neb., March 9, 1887; Harvard Medical School, Boston, 1913; specialist certified by the American Board of Pathology; member of the American Trudeau Society, American Association of Pathologists and Bacteriologists, and the American Society for Experimental Pathology; associate professor of pathology at Columbia University College of Physicians and Surgeons in New York City; formerly associate professor of pathology at the University of Wisconsin Medical School in Madison; veteran of World War I; in 1954 received the Trudeau medal, the annual award of the National Tuberculosis Association, for his contributions in tuberculosis research; for 25 years connected with the Metropolitan Life Insurance Company as director of the Hegeman Memorial Research Laboratory at Mount McGregor Sanatorium in Mount McGregor, N. Y.; served as principal pathologist for the New York State Tuberculosis Service at Hermann M. Biggs Memorial Hospital in Ithaca; pathologist at the Veterans Administration Hospital in Sunmount, where he died June 30, aged 69, of coronary thrombosis.

Blumenthal, Robert Warren ⊕ Milwaukee; born in Columbus, Aug. 28, 1881; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; specialist certified by the American Board of Internal Medicine; formerly on the faculty of the Marquette University School of Medicine; past-president of the Medical Society of Milwaukee County and the Milwaukee Academy of Medicine; at one time councilor of the 12th District of the State Medical Society of Wisconsin; fellow of the American College of Physicians; veteran of World War I; prior to his retirement served on the staffs of St. Luke's, Evangelical Deaconess, and Milwaukee County hospitals; for many years editor of the *Milwaukee Medical Times;* died July 1, aged 74, of heart disease and diabetes mellitus.

Mallon, Francis Edward ⊕ Brooklyn, N. Y.; born in Brooklyn June 18, 1895; Long Island College Hospital, Brooklyn, 1919; clinical associate professor of ophthalmology at his alma mater, now known as the State University of New York College of Medicine; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past-president of the Brooklyn Ophthalmological Society; active in the founding of the Catholic Physicians Guild of Brooklyn; surgeon on the staff of the Brooklyn Eye and Ear Hospital; consulting ophthalmologist at St. Mary's Hospital; died in Avon, N. J., June 24, aged 61.

Brooks, Clark David ⊕ Detroit; born in Southfield, Mich., Aug 10, 1878; Detroit College of Medicine, 1905; served on the faculty of his alma mater, now known as Wayne University College of Medicine; fellow of the International College of Surgeons and the American College of Surgeons; specialist certified by the American Board of Surgery; formerly member of the city board of education; veteran of World War I; on the staffs of the City of Detroit Receiving Hospital, Woman's Hospital, Harper Hospital, and the Highland Park (Mich.) General Hospital; died May 28, aged 77, of coronary thrombosis.

⊕ Indicates Member of the American Medical Association.

Laws, James Warren ⊕ El Paso, Texas; Memphis (Tenn.) Hospital Medical College, 1898; member of the American College of Chest Physicians and the American Trudeau Society; fellow of the American College of Physicians; past-president of the El Paso County Medical Society; employed by the City-County Health Department as director of El Paso tuberculosis control and in charge of the tuberculosis department of the City-County Hospital, now El Paso General Hospital, from 1938 to 1951; at one time medical director of the Hendricks-Laws Sanatorium; died June 15, aged 82, of heart disease.

Ambrose, Charles Seward, Visalia, Calif.; St. Louis College of Physicians and Surgeons, 1904; served as health officer of Tulare County; died June 25, aged 78.

Atwood, Charles Herbert, Grants Pass, Ore.; Hahnemann Medical College of the Pacific, San Francisco, 1902; died June 2, aged 75.

Austin, De Witt Ray ⊕ Charlotte, N. C.; Jefferson Medical College of Philadelphia, 1917; died July 2, aged 64, of ventricular fibrillation and hypertension.

Bredehoft, Julius Curt ⊕ Boerne, Texas; Medico-Chirurgical College of Kansas City, Mo., 1900; died May 14, aged 79, of carcinoma of the right lung.

Carpenter, Claire Harold ⊕ Detroit; the Hahnemann Medical College and Hospital, Chicago, 1918; for many years associate director of the Grace Hospital, Northwestern Branch, where he died June 27, aged 63, of coronary disease.

Casto, Charles Clayton ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1921; on the staffs of the Huron Road and St. Luke's hospitals; died July 1, aged 68, of congestive heart disease.

Chimene, Eugene Opet, Forest Hills, N. Y.; Rush Medical College, Chicago, 1919; member of the Medical Society of the State of New York; died June 26, aged 60, of coronary arteriosclerosis.

Crawford, James Davidson ⊕ New Castle, Pa.; Harvard Medical School, Boston, 1924; veteran of World War I; a director of the First Federal Savings and Loan Association; trustee of the Westminster College in New Wilmington; founding fellow of the American College of Obstetrics and Gynecology; died July 18, aged 57.

Gellenbeck, Albert Henry, Cincinnati; University of Cincinnati College of Medicine, 1933; member of the Ohio State Medical Association; on the staff of the Good Samaritan Hospital, where he died June 13, aged 58, of heart disease.

Howley, Ambrose N., Norfolk, Neb.; Lincoln (Neb.) Medical College of Cotner University, 1907; served on the faculty of his alma mater; died June 4, aged 72, of cancer.

Johnston, Kenneth Lawrence ⊕ Oskaloosa, Iowa; University of Illinois College of Medicine, Chicago, 1914; fellow of the American College of Surgeons; formerly vice-president of the Iowa State Medical Society; on the staff of the Mahaska County Hospital, where he died June 9, aged 65, of cerebral metastasis from carcinoma of the bladder.

Jordan, Ralph Ensign ⊕ Emporia, Kan.; University of Kansas School of Medicine, Kansas City, 1940; member of the American Academy of General Practice; veteran of World War II; on the staffs of St. Mary's Hospital and the Newman Memorial County Hospital, where he died July 10, aged 39, of bulbar poliomyelitis.

King, Charles Royal ⊕ Toledo, Ohio; Toledo Medical College, 1907; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; veteran of World War I; for many years member of the board of directors of the University of Toledo; at various times on the staffs of the St. Luke's and Riverside hospitals, and St. Vincent's Hospital, where he died June 22, aged 70.

King, Edgar Addison ⊕ Minneapolis; Chicago Homeopathic Medical College, 1887; Rush Medical College, Chicago, 1895; veteran of World War I; affiliated with the health department of the city of Minneapolis; on the staffs of St. Mary's and Northwestern hospitals; died in Eitel Hospital June 1, aged 91, of cerebral thrombosis.

Kinsella, Michael Allen, New Britain, Conn.; Tufts College Medical School, Boston, 1912; fellow of the American College of Surgeons; served on the staffs of the Bradley Memorial Hospital in Southington and the New Britain General Hospital, where he died June 28, aged 72.

Komaroff, Hyman M. ⊕ Brooklyn, N. Y.; Long Island College Hospital, Brooklyn, 1916; on the staff of the Crown Heights Hospital; died May 31, aged 67, of coronary disease.

Kurtz, Clarence Suplee, Malvern, Pa.; Bellevue Hospital Medical College, New York City, 1890; an associate member of the American Medical Association; member of the Medical Society of the State of Pennsylvania; veteran of World War I; member of the staff of the County Branch of Rush Hospital for Consumption and Allied Diseases; formerly a member of the Malvern Library and the Malvern Fire Company; died May 15, aged 89.

Lacey, R. C., Centerville, Texas; Missouri Medical College, St. Louis, 1890; died in Crockett June 7, aged 88, of myocardial infarction.

Lamb, Jay Hugh, St. Louis; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1914; died in the Lutheran Hospital July 5, aged 67, of chronic myocarditis and chronic hypertrophic arthritis.

Leenhouts, Abraham ⊕ Holland, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; veteran of World War I; for many years member of the board of education; served as campus physician at Hope College; honorary member of the staff of the Holland City Hospital, where he died July 3, aged 89, of cancer of the stomach and liver.

Leinwand, Irving ⊕ New York City; Rush Medical College, Chicago, 1937; interned at the Sydenham Hospital; veteran of World War II; served on the staffs of Bellevue and St. Clare's hospitals; on the staff at the University Hospital, where he died July 13, aged 45.

Lemay, Alfred Mederic, Brockton, Mass.; Tufts College Medical School, Boston, 1913; member of the Massachusetts Medical Society; school physician; died June 3, aged 68, of pulmonary embolism.

Leone, Vincent David, Eggertsville, N. Y.; University of Buffalo School of Medicine, 1925; an associate member of the American Medical Association; fellow of the American College of Surgeons; past-president of the Niagara County Medical Society and the Tuberculosis Association of Niagara County; veteran of World War II; on the staff of the Niagara Falls (N. Y.) Memorial Hospital; died in the Veterans Administration Hospital, Buffalo, July 6, aged 55, of pneumonia and paralysis agitans.

Light, Arthur John ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1908; on the staff of the Deaconess Hospital, where he died June 12, aged 71, of cerebral hemorrhage and Parkinson's disease.

Livermore, Ira Warner, Gowanda, N. Y.; University of Buffalo School of Medicine, 1899; an associate member of the American Medical Association; for many years school physician; during World War I served as a major first with the Army Medical Corps in the United States and later with the Royal Medical Corps in England; honorary member, medical staff at the Tri-County Memorial Hospital, where he died June 27, aged 84, of arteriosclerosis and uremia.

Lufburrow, Charles Bromwell, Plainfield, N. J.; Baltimore Medical College, 1897; served as city physician and president of the board of health; an associate member of the American Medical Association; first emeritus consultant surgeon, formerly chief surgeon and president of the medical board at the Muhlenberg Hospital, where he died June 27, aged 83, of mediastinal tumor.

McCord, Malcolm Christian ⊕ Denver; University of Michigan Medical School, Ann Arbor, 1945; instructor in medicine, University of Colorado School of Medicine; specialist certified by the American Board of Internal Medicine; certified by the National Board of Medical Examiners; captain, Army of the United States, from 1946 to 1948; served on the staffs of the Colorado General and Denver General hospitals; died May 27, aged 35.

FOREIGN LETTERS

BRAZIL

Dementia Paralytica Juvenilis.—Dr. Waldemar Cardoso, of the Juquery Psychiatric Hospital, São Paulo, reported to the Associacão Paulista de Medicina on a series of 45 patients with dementia paralytica, whose age on admission varied between 7 and 26 years. The diagnostic criteria used were (1) syphilis in one of the parents; (2) syphilis in the patient; (3) early onset of the disease; (4) absence of history of sexual contact; (5) physical stigmas of congenital syphilis; and (6) serologic findings of neurosyphilis. Most patients did not fulfill all six criteria, but the presence of the third, sixth, and at least one other was required. The speaker concluded that the ratio between male and female patients was about 7:10. The age at the onset was most frequently between 11 and 20 years (range 5 to 23 in this series). Maternal syphilis was proved in 28 patients. Nonsyphilitic neuropsychopathies were present in members of the immediate family of 28 patients, with alcoholism predominating. Physical and mental anomalies of development were noted in the case history of 32. The onset may be insidious (in patients previously showing mental deficiency) or acute (in those who were mentally normal). Neurological accidents consequent to other early manifestations of neurosyphilis were present in 16 patients, with convulsions and paralyses predominant. The most frequent physical stigmas of congenital syphilis were dental malformations and anomalies of skeletal development. The neurological examination revealed alterations of the patellar and achillean reflexes in 40 patients, other frequent neurological findings being dysarthria, tremor, and disturbed equilibration. Argyll-Robertson's sign was present in 37. The most frequent clinical form was simple dementia. The incidence of taboparesis in dementia paralytica juvenilis is lower than in the adult form. Half of the patients obtained good results with malariotherapy followed by specific chemotherapy, but from the qualitative standpoint the results were inferior to those observed in the adult form, with only three patients showing complete remission. The therapeutic results were more favorable in direct ratio to the normality of mental development up to the onset of the disease, to the lateness of the onset, and to the promptness of beginning treatment.

Percutaneous Splenoportography and Splenomanometry.—Dr. Ary L. de Almeida and co-workers in *Revista do Hospital das clinicas* (11:135, 1956) reported that they performed 147 splenoportographies on 112 patients, with only one fatal hemorrhage. This occurred in a patient who had a malignant reticuloendotheliosis. Material was obtained from normal spleens and from those of patients with various types of splenomegaly, several types of hepatic cirrhosis, extrahepatic portal obstruction, and portocaval shunt. The authors concluded that percutaneous splenoportography permits a good evaluation of circulatory conditions in portal territory, disclosing the different changes produced by hepatic and prehepatic conditions and furnishing information that may lead to adequate therapy. Percutaneous intrahepatic manometry was performed on 97 persons, some normal and some with various types of splenomegaly, congestive heart failure, several types of cirrhosis, extrahepatic portal obstruction, and portocaval shunt. Comparing data obtained before, during, and after the opening of the abdomen, the authors found that the pressure falls during anesthesia and with the opening of the abdominal wall. When measured with the abdominal wall open, intrasplenic and portal pressures were found to be identical. On this basis the authors judge transcutaneous splenomanometry a good method for the evaluation of portal pressure.

Complications in Operations on the Thyroid.—Drs. Josias de Andrade Sobrinho and E. Salvador Sapia reported in *Revista paulista de medicina* (48:425, 1956) a study on complications after 143 operations on the thyroid. They recognized two groups of complications. The first group, depending on hyperthyroidism and to a certain extent poor preoperative care, included mainly the postoperative thyrotoxic crises and, in lesser degree, operative hemorrhages. The second group, depending on difficulties or technical faults, included lesions of the laryngeal nerves, postoperative hemorrhages, and hypoparathyroidism.

INDIA

Impulse Generation in the Atrioventricular Node.—Das and Arora (*Indian J. M. Sc.* 10:255, 1956) gave epinephrine, levarterenol, acetylcholine, and atropine to 35 dogs. The actions of the autonomic agents on the impulse generation in sinoauricular and atrioventricular nodes were similar qualitatively but different quantitatively. Following atropinization, the heart rate increased by 21.6% in sinoauricular rhythm and 5.5% in atrioventricular rhythm, showing low vagal tone in the atrioventricular node. The atrioventricular node showed more response to acetylcholine and less to cardioaccelerators than did the sinoauricular node. Cardioaccelerators and sometimes atropine changed atrioventricular rhythm with simultaneous atrial and ventricular activation to atrioventricular rhythm with preceding atrial activation. The actual mechanism could not be conclusively demonstrated.

Chloramphenicol, Bone Marrow, and Typhoid.—M. J. Shah and co-workers (*Journal of the Association of Physicians of India*, vol. 4, April, 1956) reported a series of 24 patients with blood cultures positive for typhoid and/or a positive Widal test. Blood cell counts and bone marrow studies were made on the day of admission. The patients were then given chloramphenicol. An average of 15 gm. of the drug was given in 10 or 11 days. During this period, peripheral blood cell counts were made every fourth day and bone marrow studies were repeated on the last day of the drug therapy. In eight patients there was bone marrow depression before the start of the treatment, probably due to typhoid toxemia, the total leukocyte count being below 25,000 per cubic millimeter; however, the differential count was within normal limits. In all these patients there was marked improvement in the total blood cell count at the end of treatment. In three the bone marrow was initially normal but showed a depression after treatment with chloramphenicol; two showed a megaloblastic reaction in a second marrow study, while in three others the marrow was not affected quantitatively but there was selective depression of either the erythroid or myeloid series or both. Nine patients showed no change, quantitative or qualitative. In the second, third, and fourth groups the drug seems to have been responsible for the bone marrow depression. In five of these patients, the peripheral blood findings remained unaltered while two showed a megaloblastic reaction. Since bone marrow shows evidence of early hypoplasia in the absence of peripheral blood changes, a routine study of the bone marrow would seem to help in early detection of patients whose hemopoietic system may show hypersensitivity to chloramphenicol.

Home for Blind.—The first industrial home for blind adults will be opened soon in Bombay. In the first year, 50 inmates will be admitted. Facilities for training in weaving, cane-work, basketry, brush-making, music, and braille will be provided. Preference will be given to the blind from the rural areas, and they will be given intensive training in agriculture, poultry raising, and allied occupations. There are 70 institutions for the blind in India, of which over 60 are limited to the blind under the age of 18 and none provide agricultural training. Facilities for training the adult blind are grossly inadequate, but the necessity for such training is now recognized.

Plasma Cell Mastitis.—G. V. Talwalkar reported 12 cases of plasma cell mastitis in a series of 2,061 breast specimens examined (*Indian J. M. Sc.* 10:375, 1956). In 8 of the 12 cases, frozen sections were made at the time of operation. All but one of the 12 patients had borne children. In all cases the presence of a mass in the breast brought the patient to the hospital. Only three complained of pain. There was a white discharge from the nipple in one of these. The nipple was retracted in three. The mass was fixed to the skin in three, and one had the so-called pigskin appearance. The lump was present usually behind and around the areola. It was firm or hard, with well-defined margins. Axillary lymph nodes were palpable in six patients. Two of the 12 patients were thought to have plasma cell mastitis on the basis of signs and symptoms of acute inflammation, 5 were thought to have carcinoma clinically; 2 had a diagnosis of chronic mastitis; one was thought to have an acute abscess; and in one patient the diagnosis lay between carcinoma, tuberculous mastitis, and fibroadenoma. In two of the eight cases in which frozen sections were made, a diagnosis of plasma cell mastitis was suggested; one was found to be chronic mastitis, in three only a chronic inflammatory process could be seen; in one an erroneous diagnosis of carcinoma was made; and diagnosis was deferred in the remaining case. The cut surface in six specimens showed scattered white areas suggestive of chronic mastitis; four showed small soft necrotic yellow-brown areas; and the remaining two showed an abscess cavity filled with thick yellow purulent material. Microscopically all showed a predominance of plasma cells. Besides these, large macrophages were also conspicuous. Lymphocytes, neutrophils, and sometimes eosinophils were seen. The epithelial cells of the duct were regular in shape and size. Occasionally plasma cells of varying sizes with hyperchromic nuclei and binucleate forms were encountered. In eight patients, local excision of the mass was performed, and in the remaining four a mastectomy was performed. Local recurrence occurred in only one of these patients. Malignant changes are rarely associated with this condition, but local recurrence of the inflammatory process is not uncommon.

Piperazine for Threadworms.—C. J. Modi and co-workers gave a syrup containing 100 mg. of piperazine hexahydrate per cubic centimeter to a series of 24 patients with threadworm infestation (*Indian J. M. Sc.* 10:278, 1956). Piperazine is believed to act by inducing a state of narcosis in the worms. Twenty-two of the patients were given 50 mg. of the drug per kilogram of body weight, the drug being administered twice a day in equal doses on an empty stomach, with administration continued for seven days. This was followed by a rest period of one week, after which the treatment was repeated for another seven days. Fifteen patients took this full course of treatment. Of these, 11 were cured, 3 achieved only symptomatic relief, and one was not improved. Seven patients took an inadequate amount of the drug. Two patients were given 75 mg. per kilogram of body weight per day for 10 and 14 days respectively. The first of these showed ova in the stools 21 days after the end of treatment and the second was ova-free when seen 40 days after termination of the treatment. The general pattern of response was much the same in most of the patients. Worms appeared in great numbers in the stools on the second and third day of treatment, and by the end of the fourth day most of the patients were symptom-free. For a complete eradication of infestation, treatment for a period of less than 14 days is generally not effective. Even with the full course of treatment, piperazine therapy is effective in only about 73% of the patients.

ITALY

Abortion Due to Psychic Trauma.—The frequency of abortion due to psychic trauma is less than is generally believed. The pathogenesis and the typical clinical manifestation are still not clearly defined. In order to throw more light on these two points, Professor Meloni reported on two cases in *Rivista di ostetricia e ginecologia* (no. 1, 1956). One might think that violent emotions would cause an abrupt neurovegatative response that at first is mainly adrenergic, with contraction of the cervical muscles and ischemia of the uterus followed by a cholinergic response, with dilatation of the cervix and congestion due to stases at the level of the uterodecidual region. The two cases observed by the author demonstrated the importance of such complementary causal factors as hyperthyroidism and neurovegative lesions.

Meeting of Neurologists.—The Italian Neurological Society held its 12th annual meeting in Padua in April. Professor Berlucchi of Padua said that most encephalitides are caused by filtrable viruses. The most important of these are rabies, lethargic encephalitis, Japanese encephalitis, Australian encephalitis, and Russian spring-summer encephalitis. The diagnosis in each case is made by serologic tests. Leptospira, Treponema pallidum, and some Plasmodium organisms may cause encephalitis, but molds seldom do.

Professor Pinelli of Pavia said that electroencephalographic examination reveals characteristic alterations when acute encephalitis is present. The typical finding in these cases is a slow and diffuse disorder in the rhythm. This must be evaluated in the light of all other clinical data. In the subacute and progressive encephalitis of Van Bogaert, groups of slow waves of great amplitude that repeat themselves at regular intervals of six to nine seconds appear. Professor Cazzullo of Milan said that the demyelinizing encephalomyelitides could be classified as postexanthematous, parainfective, postvaccinal, cryptogenic disseminated, hemorrhagic, and sclerosal. Antibiotics and corticotropin can be used in their treatment.

Professors Gozzano and Vizioli of Bologna said that epileptic attacks may be precipitated by retention of water, alkalosis, anoxemia, hypoglycemia, and certain afferent stimuli. The neuronal discharge that manifests itself as epileptic crisis is caused by a transitory but marked disturbance of the cellular metabolism that becomes increasingly rapid. This causes imbalances in the distribution of the extracellular and intracellular electrolytes, especially potassium. The speakers concluded that, for the Jacksonian form, which is the most typical example of epilepsy with a circumscribed focus, the propagation of the discharge comes about either as a synaptic transmission from one point of the cortex to another or by contiguity, i. e., through the intercortical connections, but when the epileptic crisis is general, the cortico-cortical transmission is no longer sufficient to explain the suddenness and simultaneousness of participation of the whole brain in the crisis. Some other mechanism must intervene. This suggests that in the brain there is a structure with diffused projection that is connected with all the cerebral motor centers. This could be the reticular formation of the thalamus and of the encephalic trunk. The role of the rhinencephalic formations in the mechanism of epileptic crisis is unknown. Professors Rigotti and Schergna of Padua reported a series of 1,195 patients who were treated by different methods. In general, grand mal epilepsy responded best to treatment. In the period 1940 to 1949 the speakers relied on bromides, barbital, and diphenylhydantoin sodium; from 1950 to 1953 they used trimethadione, methylphenylethylhydantoin, and phenacemide as well; and in 1954 and 1955 primidone, methylphenylsuccinamide, and acetazolamide were also used. The newer drugs were used when the older drugs failed to help the patient. In the first period good results were obtained in 76.1% of the patients, in the second in 81%, and in the third in 82.7%. So many toxic side-actions were associated with the new drugs that chief reliance must still be placed on phenobarbital and diphenylhydantoin.

PERU

New Public Health Building.—On July 20, the new home of the Department of Industrial Hygiene, Ministry of Public Health, was opened. The equipment was provided by the Inter-American Cooperative Service of Public Health. One of the chief problems in industrial health is the prevention of pneumonoconiosis in coal miners and the enactment of adequate social laws to compensate those who contract it. On July 21, the Social Assistance Center was inaugurated, and two days later the new 1,000-bed hospital for the Army, which is one of the largest of Peru, was opened. On July 24, the Great Hospital for the Employee, a 17-story structure under the jurisdiction of the Agency of Social Insurance for the Employee, was opened. Among the special features of this 900-bed hospital are a special chamber to handle radioactive isotopes and a landing field for helicopters on the roof. Two other hospitals are being built, both at Arequipa: one with a capacity of 400 beds for tuberculous patients and the other for the Agency of Social Insurance of the Employee for Southern Peru, with a capacity of 250 beds.

SWEDEN

Treatment of Psychoses.—About 85% of the inmates of state-owned insane asylums have a record of more than one year spent in such an asylum. The value of a more dynamic program of treatment for these patients is being recognized. At the St. Lars mental hospital in Lund, an experiment was started in November, 1955, with a view to giving the patients congenial employment. In *Nordisk medicin* (vol. 55, June 7, 1956) an account of this experiment is given by Dr. Gerdt Wretmark. Occupational therapy was limited to a section of this hospital housing 32 women, mostly schizophrenic, whose ages ranged from 34 to 81 years. The atmosphere of this section at the beginning of the experiment was characterized by passivity on the part of the patients and a sense of frustration on the part of the staff. The nurses and patients were grouped in working teams, each with its special duties and functions. Groups of patients were put to work for about three hours a day on some industrial occupation for which payment was made. The gymnastic exercises became so popular that all but two of the patients were induced to take part in them. The spirit of comradeship was enhanced when the physicians discarded their white suits and joined in the teamwork. The changeover from a static to a more dynamic rhythm made the nurses feel more tired but also happier than they had been before. Though many unfavorable circumstances hampered this group psychotherapy, the improvement in the general atmosphere was encouraging for both staff and patients. To achieve the best results it will be necessary to increase the asylum staffs and to encourage study visits to the most progressive asylums in the country.

Unsuitable Patients in Hospital Beds.—A recent study showed that general hospitals in Sweden housed many patients with chronic diseases not requiring the skilled and costly treatment indicated for acute cases. In order to determine whether, on the other hand, nursing homes for domiciliary care house some patients in need of active treatment, Berg and Tillman, as reported in *Svenska läkartidningen* for June 1, examined the 294 inmates of seven such homes and found that 177 were really in need of institutional treatment and that 65 could be treated just as well at home. Thirty-six patients had psychiatric conditions and should not have been in homes for patients with chronic physical ailments. There were also 16 patients with acute conditions who needed hospital care. The 177 patients found to be suitable for care in nursing homes included 55 suffering from cerebral hemorrhages. Malignant tumor was next in the order of frequency with 29, and chronic articular rheumatism was third with 24. The authors conclude that care of the aged and of the chronically ill has hitherto been too passive and that a more active policy is needed.

Jaundice from Chlorpromazine.—With the growing popularity of chlorpromazine in psychiatry, its ability to provoke jaundice has attracted so much attention that the Swedish Ministry of Health has instituted a statistical study of the problem in the state mental hospitals. This study yielded a frequency rate of 0.57%. At the St. Lars mental hospital in Lund, 357 patients were given chlorpromazine between March, 1954, and May, 1955. Of these, the 10 in whom jaundice developed ran a remarkably uniform course lasting a week or two and showing no sign of permanent damage to the liver. Commenting on these cases in *Svenska läkartidningen* for June 15, Dr. Ekdahl and co-workers stated that chlorpromazine has become almost indispensable in psychiatry; but, as the indications for it are well defined, the risk of jaundice should deter physicians from giving this drug experimentally for a variety of vague and ill-defined nervous ailments.

UNITED KINGDOM

Hypercalcemia in Infants.—The British Pediatric Association has issued the report of a subcommittee set up to consider the intake of vitamin D in infants in relation to the possibility of hypercalcemia. In 1943, the British Pediatric Association recommended a daily intake of 700 I. U. of vitamin D for infants and young children. When this recommendation was made, the fortification of infant foods with calciferol had not become standard practice. The committee wrote to 196 consultant pediatricians who between them had seen 204 patients with hypercalcemia between 1953 and 1955. The incidence was greatest in infants between 4 and 8 months of age. No case was observed in an entirely breast-fed infant. There is a fall in the califerol content of fortified infant foods and milk after issue, and in 1953 the Ministry of Food recommended the addition of 500 I. U. of vitamin D as caliciferol per ounce to allow for a maximum deterioration of 44%, thus giving a minimum of 280 I. U. per ounce. If the fortified milk is bought soon after manufacture, it may contain over 500 I. U. of vitamin D. Cereals are also fortified by manufacturers, some with 1,500 I. U. of vitamin D per ounce. If in addition to these an infant is given a teaspoonful of fortified cod liver oil under the welfare food service, it may be receiving another 700 to 800 I. U. It is thus possible for an infant receiving 1.5 pints of reconstituted dried milk, 1 ounce of fortified cereal, and a teaspoonful of fortified cod liver oil to have a daily intake of about 4,000 I. U., which is excessive.

In view of the possibility of such large intakes of vitamin D, the committee suggests that steps be taken to prevent overfortification of foods with the vitamin. It recommends (1) omitting calciferol from dried milks or limiting it to a range of figures and (2) omitting cod liver oil supplements in the case of infants fed on fortified milk. Caliciferol could also be omitted from cereals used for infants. The best solution would probably be not to fortify foods with calciferol at all but to give every infant cod liver oil of known potency.

Medical Research Council.—The annual report of the Medical Research Council (Cmd. 9787, London, Her Majesty's Stationery Office, 1956) describes the research efforts of the council up to the end of 1955. In that period over $5,500,000 was spent on research covering the whole range of medicine and allied sciences. The importance of genetics in medicine is receiving increased recognition. About 20 different natural erythrocyte antigens are known, inheritable in different combinations. Recognition of these is of growing importance in avoiding transfusion reactions and neonatal death and in settling medicolegal questions. Work is being extended concerning the blood groups in various diseases, e. g., in peptic ulcer and cancer of the stomach, in which there is a preponderance of patients with blood groups 0 and A respectively. Blood group antigens can be extracted from the gastric mucosa. Hematological and genetic research has also included the study of the sickle-cell trait, which makes the erythrocytes more liable to hemolysis but affords some protection against malaria. The examination of urine and blood by paper chromatography has advanced the study of the so-called inborn errors of metabolism such as cystinuria and phenylketonuria. Inability to metabolize phenylalanine in the diet may be the cause of mental deficiency in some children, and attempts are being made to rear infants with phenylketonuria on phenylalanine-poor diets in the hope of avoiding this mental defect. If the experiment is successful it would suggest that the results of inborn errors of metabolism can be avoided by suitable diets.

A rich harvest is being reaped in the field of cellular pathology by the introduction of new techniques such as electron, ultraviolet, and interference microscopy. The knowledge is being applied to the study of the pathology of cancer and the collagen diseases. Recent work has shown that collagen fibers are formed mostly outside the connective tissue cells in the intracellular spaces. The role of desoxyribonucleic acid in cellular pathology is being studied. When a bacteriophage attacks bacteria, the later elaborate more phage protein, and, similarly, when a virus attacks a living cell, the nucleus of the latter forms more virus protein, which is taken up by the virus particles. Radioactive isotope tracer studies have been made in research on antibodies, immunity mechanisms, and allergy. By these means it has been shown that antibodies are formed in the spleen and lymph nodes, mainly by plasma cells. When antigen and antibody react in vivo, serotonin is liberated from the blood platelets. This substance may be associated with anaphylactic reactions. Industrial psychologists state that repetitive work shows no decline in performance with fatigue, provided the worker can control the rate of work; that slight and repeated changes in working conditions give a better output than uniform so-called optimum conditions; and that it is more tiring to watch than to do a task, provided that doing it is within the capacity of the individual.

Vitamins in Embryonic Development.—Woollam and Millen (*British Medical Journal*, vol. 1, June 2, 1956) state that the modern view of the vitamins is that they are complex chemical substances, essential to life by virtue of their role in the biochemical processes of the cell. Vitamins have to be obtained from the diet because of the inability of the body to synthesize them. The increased demand by the pregnant woman for vitamins reflects the need of the embryo to build up a store of these substances, and experiments with animals indicate that if the minimum requirement is not met the embryo will either die or be born congenitally deformed. What validity such experiments have for conditions in human beings is as yet not known. It must be noted, however, that if human conditions do correspond to those in the animal the administration of vitamins during pregnancy is of little avail to the embryo. Minor degrees of experimental vitamin deficiencies produce malformations during the early months of pregnancy, at a time when even the existence of pregnancy may not be evident to the woman. In obstetric practice vitamins are commonly prescribed in the middle and late months of pregnancy. The results of the experiments with animals described above suggest that the only way in which the nutrition of the embryo can be safeguarded is by attention being directed toward the diet of women throughout their lives, and especially of girls in the later stages of adolescence. Only by reorienting our attitude in this way can we ensure that the members of the next generation will develop in bodies that provide an adequate supply of essential foodstuffs from the beginning of pregnancy.

Health Visitors Needed.—An increase of 3,500 health visitors (not visiting nurses) to a total of 11,500 is recommended (An Inquiry into Health Visiting, London, Her Majesty's Stationery Office). Health visiting emerged at the beginning of the century as specialized health education directed to mothers and children in their homes. Voluntary in origin, it is now almost exclusively a public service. The health visitor could increasingly become a family visitor, working under the professional guidance of the family physician. Her functions should primarily be health education and social advice. Diaries kept by selected visitors stressed such social problems as marital disputes, debt, and drunkenness. At present, working relationships between physicians and health visitors are thoroughly established in only a few areas. Some physicians rarely hear of the visitors except when they give conflicting advice. Because the family physician is now much more concerned with the preventive and social aspects of illness, the health visitor is admirably placed to help him. She could play an important role in mental health and care of the tuberculous. There should be experiments in shortening training. Pay and conditions should be improved.

Official Discourtesy.—Members on both sides of the House of Commons have complained about the treatment of the public by hospital authorities. Mr. Crossman (Soc.) said that Parliament had allowed the real responsibility for public relations to pass to the bureaucracy. Mr. Benn (Soc.) said that the treatment of outpatients was appalling. They must wait in a filthy room for two, three, or four hours because everybody is told to come at the same time. Mr. Maccoll (Soc.) described how he went recently to a London hospital for a simple x-ray examination. He believes that the public hangman would have been more courteous toward one of his clients than was the young lady who was operating the x-ray machine.

Dentists Form Strike Headquarters.—The 11,000 dentists in the National Health Service are setting up a body that could, if dissatisfaction over pay became acute, organize a mass withdrawal from the service. Notice that a claim for more pay is to be submitted has been given to Mr. Turton, Minister of Health, by the British Dental Association. The dentists want a rise to offset the fall in the value of money since 1950. Hospital and health center dental officers will be included in the claim. Because the association itself is precluded from organizing among its members any sort of restrictive practice, a new body, the British Dental Guild, is to be established. It will be independent of the association, whose activities it will supplement. The association will continue to frame policy. The guild will be an organization that can engage in vigorous propaganda and act on a prepared plan when the need arises. The guild and its machinery for withdrawing from the service or limiting the professional contribution of dentists would be used only as a last resort. Leaders of the profession hope that such steps will never be necessary.

Cambridge Honors Dr. Bronk.—On June 7, Cambridge conferred an honorary degree of doctor of science on Dr. D. W. Bronk, president of the American Academy of Sciences, president of the Rockefeller Foundation, and chairman of the U. S. National Research Council. In 1928-1929 he was a research fellow in medicine at Cambridge and London, and he was elected a foreign member of the Royal Society in 1948.

Getting Married.—A booklet entitled "Getting Married," which covers every angle from romance to recipes but gives "no guaranteed recipe for married happiness," has appeared with the blessing of the British Medical Association. Published in connection with *Family Doctor*, the monthly B.M.A. journal, the booklet, priced at 15 cents, is the first B.M.A.-backed attempt to present a popular guide for engaged couples. The editor, who is also editor of *Family Doctor*, said: "There is a real demand for such a book. We get scores of letters asking advice on various problems of marriage. Some are from people in their twenties who do not even know the facts of life." Articles by experts deal frankly with the sexual and psychological sides of marriage, the chances of children, matters of heredity, and even the role of the mother-in-law. The contributors include general practitioners, psychiatrists, and lay experts. The booklet discusses the material as well as the emotional side. There are beauty hints for the bride and illustrations of honeymoon spots side-by-side with psychological advice on honeymoon problems. Other articles give practical hints on such subjects as purchasing a home, legal problems, and recipes.

Parthenogenesis.—A controversy over alleged parthenogenesis is raging in the British press. A series of 19 claimants to virgin birth were interrogated, examined, and made the subject of searching tests, and, of these, one claimant appeared to show such complete identity of make-up with her daughter that there is no evidence of the involvement of a third party. These people have been the subject of a symposium (*Lancet*, vol. 1, June 30, 1956). Dr. Balfour-Lynn says that, while rigorous proof in such a case is impossible, all the evidence obtained from serologic and special tests is consistent with what would be expected in a case of parthenogenesis. He sought such identity in the blood group and subgroups, skin grafting, taste perception at a precise dilution value, and certain salivary secretions. In three of these tests complete identity was established between mother and daughter, but in skin grafting there was no success. One of the foremost authorities on genetics seized on this point as vitiating the claim, and added that one can never prove parthenogenesis by such tests and in this instance one cannot even say that a probability of of parthenogenesis in a human being has been established. Mr. Kenneth Walker made the point that blood group, taste perception, and salivary secretion are often very similar between mother and daughter even though a father exists. The *Lancet* concluded that, if a case of parthenogenesis in a human could be proved, it could not be more frequent than the birth of sextuplets, or about once in 6.5 billion births, or in the United Kingdom once in 8,000 years.

Tomomania.—Seven major abdominal operations were carried out on a 21-year-old man, although there was nothing wrong with him. He simulated the complaints, fooled the London Hospital for a while, and eventually went to the Middlesex Hospital. The patient had been placed under supervision for stealing furniture and used hospitalization as a means of asylum. He repeatedly broke parole and was returned to prison for six months.

CORRESPONDENCE

DRUG EVALUATION AND BASIC RESEARCH UNITS IN STATE HOSPITALS

To the Editor:—The number of new drugs being introduced for the treatment of the mentally ill, the lack of a standardized system of reporting treatment results, and the conflicting reports as to the effectiveness and indications for the various preparations require that a state establish its own continuing drug evaluation program. In order that such a system of evaluation may function efficiently, personnel must be trained to evaluate behavioral change, this evaluation should be based on direct observation that may be communicated, patients must be categorized to allow for the comparison of comparable groups, and a pattern of procedure must be established to avoid delay in implementing the testing of new products. In addition to the immediate need for the determination of the effectiveness of a recommended therapy, a basic research program must be encouraged by providing specialized personnel and the necessary laboratory facilities for the psychiatrist and those in other disciplines interested in doing research.

A manufacturer may supply a hospital with a drug to investigate, and, although members of the staff may be interested in doing the evaluation, unless those interested are relieved of some service responsibility and are given secretarial help in obtaining patients' records and permission from the relatives, the product may gather dust or be tried on too few patients to allow of a significant determination. The physician responsible for establishing the usefulness of a medicament needs a sizable group of patients on whom the preparation may be tested. He should also have statistical help available to validate his results as well as assistance in preparing the manuscript. If a preparation is used on a few patients without the benefit of a control group, follow-up studies, or placebo, any change occurring during the trial period may be attributed to the drug without consideration of the factors of increased attention and interest or of spontaneous remission. If the preparation is found to be lacking in therapeutic effectiveness, the project may be dropped without the staffs in other hospitals throughout the state being informed, and consequently they must repeat the trial to gain the same information.

The large number of patients for whom a psychiatrist in a state hospital is often responsible makes it unrealistic to expect him to record frequent detailed observations on the charts of a sizable number of patients receiving a new preparation. Consequently, this responsibility may then be shifted to the nursing staff; if there is an inadequate number of nurses, the determination of a treatment's effectiveness may be left to the judgment of the ward personnel. The valid evaluation of a treatment requires frequent observations and interviews with the patients, using some standardized method of collecting and recording information before, during, and after the trial. It is of particular importance that the history and pretreatment behavior be considered; this requires a time-consuming amount of clerical work. The laboratory facilities of a state hospital and the available laboratory personnel may be hard pressed to do repeatedly blood studies and liver function and kidney function tests that may be necessary for the determination of the toxicity of a newly introduced medicament. These factors make it difficult for a psychiatrist in a state hospital to carry on clinical research while responsible for a full service load. Frequently, the facilities for doing basic research and treatment evaluation are located in medical centers, while the vast majority of patients needing treatment are housed in geographically isolated institutions where neither the personnel nor the equipment is available for doing the work.

In an effort to solve some of these problems and to expedite the clinical evaluation of new drugs for the mentally ill, particularly the tranquilizers, research units have been established in state hospitals in Nebraska. These units consist of a psychiatric nurse, a technician, and a secretary; a project is planned, the methodology is determined, and the personnel of these units act to aid the physician in charge of the project to carry it to completion. Initially, the secretary groups the patients by age, sex, diagnosis, and time in the hospital. Permission is then sought from the relative or guardian for a clinical trial with medicaments or procedures that are under investigation but not yet approved. Once all the patients in a hospital are categorized and permission is obtained from agreeable relatives, a source of clinical material becomes available and a procedure or medicament may be tested on comparable groups of patients immediately. This prevents a prolonged delay in making a new medicament available for the treatment of patients with chronic conditions and, at the same time, avoids the administration to large numbers of patients of an ineffective and frequently costly medicament about which there may be conflicting reports.

In addition to the units in the state hospital, basic research is encouraged by providing biochemists, a statistician, technical personnel, and laboratory equipment. The Nebraska Psychiatric Institute, located on the medical school campus, acts as a "central supply" for these specialized research personnel and for expensive laboratory equipment, which is issued to a particular hospital as the need arises, and when such equipment is no longer in use it is returned to this central area. This system of supply avoids duplication of expensive laboratory equipment and allows for a fuller use of technical personnel. A state research director coordinates the program to prevent duplication and delay by making regular visits to the participating hospitals and maintaining contact with their staffs.

PALATINE PETECHIAE

To the Editor:—Whenever a helpful physical sign, laboratory test, or a specific therapy is uncovered, it obviously should be reported carefully, critically, and objectively, even if only a small series. I do not wish to start a correspondence argument over a seemingly minor issue, but the phenomenon of palatine petechiae described in The Journal (161:592 [June 16] 1956), in "Palatine Petechiae, an Early Sign in Infectious Mononucleosis," by Capt. C. B. Shiver and associates, has been so helpful to many of us over the past few years that I believe an attempt should be made to give some credit to observations distinctly antedating those of the authors in 1955. Since no challenge to their claim of a first report of this sign in the literature has yet appeared in your correspondence section, I feel obliged to point out that palatine petechiae had been adequately described and photographed in the literature as early as 1953 by Dr. Charles E. Bender of Seattle. In an article in the *Northwest Medical Journal* (52:922, 1953) entitled "The Treatment of Infectious Mononucleosis with Corticotropin," this sign of palatine petechiae was mentioned by Bender and Houghton in case history no. 5 but was not belabored in the text of the article. In the *Journal-Lancet* (74:7, 1954), there is an excellent article, "The Value of Certain Signs in Presumptive Diagnosis of Infectious Mononucleosis," by Bender, with complete descriptions and a photograph of this valuable clinical sign. When I was associated with Bender in 1952, he pointed out many examples of this helpful sign from among his personal experiences with more than 700 cases of laboratory-proved infectious mononucleosis.

There are also other helpful signs in the pharynx suggestive of infectious mononucleosis, such as the glossy edema of the uvula described by Ravenna in 1948 and the frequent pure white pasty tonsillar exudate (when tonsils are present) mentioned by Rammelkamp in 1950, and these may be existent with the sign of palatine petechiae but not necessarily so. I realize that perhaps the European literature, with its former emphasis on physical signs, may well contain even prior references to this sign and do not suggest that Bender's name be assigned to this helpful sign—palatine petechiae in infectious mononucleosis.

of work; that slight and repeated changes in working conditions give a better output than uniform so-called optimum conditions; and that it is more tiring to watch than to do a task, provided that doing it is within the capacity of the individual.

Vitamins in Embryonic Development.—Woollam and Millen (*British Medical Journal*, vol. 1, June 2, 1956) state that the modern view of the vitamins is that they are complex chemical substances, essential to life by virtue of their role in the biochemical processes of the cell. Vitamins have to be obtained from the diet because of the inability of the body to synthesize them. The increased demand by the pregnant woman for vitamins reflects the need of the embryo to build up a store of these substances, and experiments with animals indicate that if the minimum requirement is not met the embryo will either die or be born congenitally deformed. What validity such experiments have for conditions in human beings is as yet not known. It must be noted, however, that if human conditions do correspond to those in the animal the administration of vitamins during pregnancy is of little avail to the embryo. Minor degrees of experimental vitamin deficiencies produce malformations during the early months of pregnancy, at a time when even the existence of pregnancy may not be evident to the woman. In obstetric practice vitamins are commonly prescribed in the middle and late months of pregnancy. The results of the experiments with animals described above suggest that the only way in which the nutrition of the embryo can be safeguarded is by attention being directed toward the diet of women throughout their lives, and especially of girls in the later stages of adolescence. Only by reorienting our attitude in this way can we ensure that the members of the next generation will develop in bodies that provide an adequate supply of essential foodstuffs from the beginning of pregnancy.

Health Visitors Needed.—An increase of 3,500 health visitors (not visiting nurses) to a total of 11,500 is recommended (An Inquiry into Health Visiting, London, Her Majesty's Stationery Office). Health visiting emerged at the beginning of the century as specialized health education directed to mothers and children in their homes. Voluntary in origin, it is now almost exclusively a public service. The health visitor could increasingly become a family visitor, working under the professional guidance of the family physician. Her functions should primarily be health education and social advice. Diaries kept by selected visitors stressed such social problems as marital disputes, debt, and drunkenness. At present, working relationships between physicians and health visitors are thoroughly established in only a few areas. Some physicians rarely hear of the visitors except when they give conflicting advice. Because the family physician is now much more concerned with the preventive and social aspects of illness, the health visitor is admirably placed to help him. She could play an important role in mental health and care of the tuberculous. There should be experiments in shortening training. Pay and conditions should be improved.

Official Discourtesy.—Members on both sides of the House of Commons have complained about the treatment of the public by hospital authorities. Mr. Crossman (Soc.) said that Parliament had allowed the real responsibility for public relations to pass to the bureaucracy. Mr. Benn (Soc.) said that the treatment of outpatients was appalling. They must wait in a filthy room for two, three, or four hours because everybody is told to come at the same time. Mr. Maccoll (Soc.) described how he went recently to a London hospital for a simple x-ray examination. He believes that the public hangman would have been more courteous toward one of his clients than was the young lady who was operating the x-ray machine.

Dentists Form Strike Headquarters.—The 11,000 dentists in the National Health Service are setting up a body that could, if dissatisfaction over pay became acute, organize a mass withdrawal from the service. Notice that a claim for more pay is to be submitted has been given to Mr. Turton, Minister of Health, by the British Dental Association. The dentists want a rise to offset the fall in the value of money since 1950. Hospital and health center dental officers will be included in the claim. Because the association itself is precluded from organizing among its members any sort of restrictive practice, a new body, the British Dental Guild, is to be established. It will be independent of the association, whose activities it will supplement. The association will continue to frame policy. The guild will be an organization that can engage in vigorous propaganda and act on a prepared plan when the need arises. The guild and its machinery for withdrawing from the service or limiting the professional contribution of dentists would be used only as a last resort. Leaders of the profession hope that such steps will never be necessary.

Cambridge Honors Dr. Bronk.—On June 7, Cambridge conferred an honorary degree of doctor of science on Dr. D. W. Bronk, president of the American Academy of Sciences, president of the Rockefeller Foundation, and chairman of the U. S. National Research Council. In 1928-1929 he was a research fellow in medicine at Cambridge and London, and he was elected a foreign member of the Royal Society in 1948.

Getting Married.—A booklet entitled "Getting Married," which covers every angle from romance to recipes but gives "no guaranteed recipe for married happiness," has appeared with the blessing of the British Medical Association. Published in connection with *Family Doctor,* the monthly B.M.A. journal, the booklet, priced at 15 cents, is the first B.M.A.-backed attempt to present a popular guide for engaged couples. The editor, who is also editor of *Family Doctor,* said: "There is a real demand for such a book. We get scores of letters asking advice on various problems of marriage. Some are from people in their twenties who do not even know the facts of life." Articles by experts deal frankly with the sexual and psychological sides of marriage, the chances of children, matters of heredity, and even the role of the mother-in-law. The contributors include general practitioners, psychiatrists, and lay experts. The booklet discusses the material as well as the emotional side. There are beauty hints for the bride and illustrations of honeymoon spots side-by-side with psychological advice on honeymoon problems. Other articles give practical hints on such subjects as purchasing a home, legal problems, and recipes

Parthenogenesis.—A controversy over alleged parthenogenesis is raging in the British press. A series of 19 claimants to virgin birth were interrogated, examined, and made the subject of searching tests, and, of these, one claimant appeared to show such complete identity of make-up with her daughter that there is no evidence of the involvement of a third party. These people have been the subject of a symposium (*Lancet*, vol. 1, June 30, 1956). Dr. Balfour-Lynn says that, while rigorous proof in such a case is impossible, all the evidence obtained from serologic and special tests is consistent with what would be expected in a case of parthenogenesis. He sought such identity in the blood group and subgroups, skin grafting, taste perception at a precise dilution value, and certain salivary secretions. In three of these tests complete identity was established between mother and daughter, but in skin grafting there was no success. One of the foremost authorities on genetics seized on this point as vitiating the claim, and added that one can never prove parthenogenesis by such tests and in this instance one cannot even say that a probability of parthenogenesis in a human being has been established. Mr Kenneth Walker made the point that blood group, taste perception, and salivary secretion are often very similar between mother and daughter even though a father exists. The *Lancet* concluded that, if a case of parthenogenesis in a human could be proved, it could not be more frequent than the birth of sextuplets, or about once in 6.5 billion births, or in the United Kingdom once in 8,000 years.

Tomomania.—Seven major abdominal operations were carried out on a 21-year-old man, although there was nothing wrong with him. He simulated the complaints, fooled the London Hospital for a while, and eventually went to the Middlesex Hospital. The patient had been placed under supervision for stealing furniture and used hospitalization as a means of asylum. He repeatedly broke parole and was returned to prison for six months.

edge only of those subjects which the theory of healing advocated and put in operation by each school requires. Were it otherwise, the legislature would be greatly hampered in the exercise of its power to protect the general health and the public from imposition and fraud.

Since the legislature, said the court, is not called upon to recognize every school of medicine and to deal with it as such, the defendants could not complain, on the ground of being unjustly discriminated against, that the legislature had not deemed it proper to recognize their school of medicine and make special provision for those desiring to practice that system by prescribing a course of study in accord with the theories which it holds for restoring health. The Maryland legislature, concluded the court, had the right to provide special regulations for these groups and to refuse to provide similar special regulations for naturopaths, who undertake to treat any and all diseases in a wide variety of fashions.

The plaintiffs finally contended that the Maryland act, as interpreted by the Maryland court, violated the antitrust laws in that it granted the exclusive privilege of practicing medicine and surgery to persons licensed by the state board of medical examiners, and thus established medicine as the preferred state system of healing, and curbed the progress of the art of maintaining health in the fields not specially regulated by the statute. The complete answer to this contention, said the court, is that the antitrust laws deal with individual activity and not with state activity, whereas all of the matters charged in the complaint as violative of the antitrust laws are regulations prescribed by the Maryland legislature. The court therefore found that the complaint did not state a cause of action and the case was dismissed. *Hitchcock, et al. v. Collenberg, et al., 140 F. Supp. 894. (Md. 1956).*

Charitable Hospitals: Immunity Limited to Injuries to Beneficiary of Charity.—This was an action for damages against a charitable hospital for injuries sustained in an elevator accident by a member of the surgical staff. The jury found that the plaintiff was not a beneficiary of the charity and returned a verdict in his favor of $50,000. From this verdict, and from the denial of a motion to set aside the verdict as excessive, the hospital appealed to the Supreme Court of New Jersey.

The plaintiff is a surgeon on the hospital's staff. His connection with the hospital dates from his graduation from medical school in 1928. He served at the hospital progressively as an intern, resident surgeon, assistant attendant in surgery, and since 1936 as attending surgeon and head of a surgery division. His surgical services to ward patients throughout these many years have been given without fee. But the plaintiff's free medical services to indigent hospital patients are not the only services he has rendered the hospital in furtherance of its mission to care for, nurture, and maintain the sick, infirm, aged and indigent. Also advantageous to the furtherance of that end have been his services in various administrative capacities. He has been president of the medical staff, a medical advisory board member, from time to time chairman of various staff committees, and a co-director of the hospital's cancer service.

The defendant hospital concedes all this but argues that the plaintiff is, in law, a beneficiary of its charity because the proofs show that before the mishap his annual income from his surgical practice resulted in major part from fees received by him for surgical operations performed in the operating rooms of the hospital, the facilities of which were made available without cost to him (the fact is, however, that, while the plaintiff paid nothing for his use of the facilities, his patients paid certain fees to the hospital) and because the proofs show also that the distinction acquired by plaintiff as a surgeon is to be attributed primarily to the experience he gained and the researches he has been able to carry on because the hospital's facilities were available to him without charge.

The evidence showed, said the Supreme Court, that the plaintiff is the originator of a widely publicized and well-regarded surgical technique used in surgical operations to relieve high blood pressure. Many persons with high blood pressure have since retained the plaintiff's services for the performance of the operation by this technique, although he has continuously practiced general surgery and has always performed many other types of operations. The plaintiff admitted during his cross examination that the work necessary to perfect his special technique and to develop his papers on the subject was done almost exclusively in the hospital's operating rooms with the use of the hospital's facilities.

The plaintiff was en route to the operating room to perform an operation for high blood pressure when he suffered an accident in the hospital elevator. His injuries were primarily to his left hand. He suffered a comminuted fracture of the left radius and a tearing of the ligaments of his left wrist with a consequent deformity and stiffness of the wrist, leaving him with a limited function thereof, both in rotation and in bending. There was also a partial atrophy of the thumb muscles. These injuries, permanent in nature, have left him with a weakened grip and loss of power in his left hand and also have impaired the delicacy of finger touch that he had before the accident. The reduced sensitivity in his left hand has also impaired his ability to employ the special technique developed by him to relieve high blood pressure.

Doubtless, said the Supreme Court, the plaintiff did realize substantial advantage from his association with the hospital, but, equally, it cannot be questioned that the hospital's mission was substantially furthered by his membership on its staff, through the free surgical services rendered by him to ward patients, through his administrative services in the various capacities mentioned, and in the dollar amounts received by the hospital from his private patients. Fairly viewed, the court continued, these proofs do not justify the classification of the plaintiff as a beneficiary of the hospital's charity. Such test as our decisions supply for differentiating a beneficiary from a stranger, the court pointed out, leans heavily upon whether the suitor is one of the "direct recipients of the charity's beneficence, an acceptor of its benefactions," whose mishap occurs in the course of "some of the continuous ministrations to the direct beneficiaries of its charitable contributions." In its emphasis upon whether the injured party is one whose connection with the charity is predominantly that of one who shares the benefits of the charity's mission, the test clearly excludes the plaintiff, whose connection with the defendant hospital is not primarily as a recipient of the benefits of the hospital's mission, but rather that of a person who importantly contributes to the furtherance of that mission. If, without access to the hospital's facilities, the plaintiff could not have attained the distinction he enjoys in his profession nor have been able to earn his livelihood in his surgical specialty, yet without his staff membership neither could the hospital have provided his free surgical services to its ward patients over the years nor have had his other services in furtherance of the advancement of its mission.

Accordingly, the Supreme Court held that the evidence supported the jury's verdict that the plaintiff surgeon was not a beneficiary of the defendant hospital and that the hospital was, therefore, not immune from liability for damages to him caused by the negligence of hospital employees. It also held that the verdict was not excessive. Judgment for the plaintiff surgeon was therefore affirmed. *Lindroth v. Christ Hospital, 123 A(2d) 10 (N. J., 1956).*

Nerve Gas Poisoning.—The manifestations and treatment of poisoning due to nerve gas are very similar to those of other organic phosphate anticholinesterase compounds, including the insecticides parathion, tetraethyl pyrophosphate, and hexaethyl tetraphosphate. The manifestations are entirely attributable to inhibition of cholinesterase enzymes in the tissues, resulting in the accumulation of acetylcholine. Ocular and respiratory effects may follow purely local exposure. Systemic absorbtion results in accentuation of the respiratory effects, in other muscarine-like symptoms, and in nicotine-like and central neural manifestations. Measures for prevention of poisoning include prompt masking and removal of liquid contamination from skin and clothing. Treatment consists of the administration of large doses of atropine, artificial respiration and oxygen when needed, and alleviation of airway obstruction.—David Grob, M.D., Manifestations and Treatment of Nerve Gas Poisoning in Man, *United States Armed Forces Medical Journal*, June, 1956.

INTERNAL MEDICINE

Pernicious Anemia Due to Dietary Deficiency of Vitamin B_{12}. M. Pollycove, L. Apt and M. J. Colbert. New England J. Med. 255:164-169 (July 26) 1956 [Boston].

A case of pernicious anemia in a 60-year-old man who had refused to ingest any food of animal origin for more than eight years is described. The anemia was caused by the dietary lack of vitamin B_{12}. This is the first time that such a cause has been established. The diagnosis was based on observation of the characteristic morphological changes of the blood and bone marrow, a serum vitamin B_{12} level of 70 micromicrograms per milliliter, which is in the range observed in patients with pernicious anemia, and a characteristic hematological response to vitamin B_{12} therapy. A pronounced drop in the serum iron level occurred after vitamin B_{12} therapy until an abnormally low level was reached at a time when the red blood cell count rose to its maximum. After stabilization of erythropoiesis, the serum iron level was restored to normal in the course of the next two months. These changes were related to variations in the rate at which iron was utilized by the bone marrow for erythropoiesis.

Vitamin B_{12} absorption, as determined by fecal elimination and urinary excretion of cobalt-60-labeled vitamin B_{12} and hepatic deposition of cobalt-60, was shown to be normal. In addition, the potency of the intrinsic factor of the patient's gastric juice was found to be normal as determined by its capacity to produce normal absorption of vitamin B_{12} in a patient with pernicious anemia in remission when it was injected simultaneously with radioactive vitamin B_{12}. The exceptional conditions that must be satisfied simultaneously for the development of pernicious anemia caused solely by dietary deficiency of vitamin B_{12} are exclusion from the diet of all meat, fish, fowl, dairy products, and unrefined grain with its products; these drastic dietary deficiencies must exist without simultaneously evoking other severe nutritional deficiencies or starvation; they must continue for at least two years; and the patients who become symptomatic by satisfying these three conditions must not receive ameliorative "shotgun" therapy before hospitalization. All four requirements were fulfilled by the patient reported on. The difficulty of simultaneously fulfilling them offers a plausible explanation of the rarity of this mode of causation. The chief significance of this case lies in its further substantiation of Castle's hypothesis by demonstrating that an extremely prolonged complete dietary deficiency of vitamin B_{12} can result in the development of severe pernicious anemia.

Plasma Pepsinogen in Peptic-Ulcer Disease and Other Gastric Disorders: A Clinical and Laboratory Evaluation. C. S. Hoar Jr. and J. R. Browning. New England J. Med 255:153-158 (July 26) 1956 [Boston].

Plasma pepsinogen is a precursor of pepsin, which is excreted in the urine and determined there as uropepsin. The simple method of Mirsky and co-workers for measuring the level of pepsinogen in the plasma in tyrosine units was tested by the authors. Results showed that the laboratory determination of plasma pepsinogen is a reliable test and apparently more satisfactory than that for urinary uropepsin. The plasma pepsinogen level remains quite constant after meals and throughout the day. Plasma pepsinogen levels were determined in 74 patients with radiologically demonstrated duodenal ulcer, in 47 patients who had had a radical subtotal gastrectomy for duodenal ulcer, in 15 patients with benign gastric ulcer, in 5 patients with histologically confirmed carcinoma of the stomach, in 33 patients with pernicious anemia, and in a control group of 89 persons who were asymptomatic or in whom gastrointestinal roentgenologic examination did not show any evidence of peptic-ulcer disease. Plasma pepsinogen levels in patients with peptic-ulcer disease were significantly higher than the normal value, and levels after subtotal gastrectomy were significantly lower than the normal. However, there was overlapping in all these groups. The mean value of the pepsinogen levels in the patients with cancer of the stomach was significantly lower than that of the control patients and of those with gastric ulcers. The pepsinogen values were universally low in patients with pernicious anemia. A low plasma pepsinogen level in the face of gastric ulceration is a strong indication of cancer. The values in patients with pernicious anemia will overlap those in patients with carcinoma of the stomach, which will always have to be considered in the differential diagnosis. Satisfactory vagotomy was followed by a drop in plasma pepsinogen level. Therapeutic doses of corticotropin (ACTH), cortisone, and compound F did not affect the plasma pepsinogen level in man.

Experimental ulcer preparations in dogs did not elevate the plasma pepsinogen level. Thoracic vagotomy in dogs significantly lowered the pepsinogen level. Vagal stimulation by insulin hypoglycemia or direct electric impulse did not cause a rise in the plasma pepsinogen level in dogs. Intravenous stimulation with corticotropin caused a significant elevation in plasma pepsinogen in gastric venous blood when compared with peripheral blood in dogs.

Idiopathic Benign Hyperglobulinemic Purpura. G. E. Seiden and H. A. Wurzel. New England J. Med. 255:170-172 (July 26) 1956 [Boston].

The occurrence of hyperglobulinemic purpura, a syndrome consisting of benign recurrent nonthrombocytopenic purpura, high erythrocyte sedimentation rate, and unexplained increase in serum gamma globulin level, is reported for the second time in a patient in the United States. A 29-year-old woman had recurrent purpura confined largely to the lower extremities, associated with an erythrocyte sedimentation rate of from 45 to 49 mm. per hour and a gamma globulin level of from 2.73 to 3.21 gm. per 100 cc. of serum, but no other demonstrable evidence of systemic disease. Muscle biopsy showed nonspecific perivasculitis. The patient continued to enjoy good health for five years despite the purpura. The vascular changes may represent a hyperergic response, of which the disturbed gamma globulin may be an other manifestation. Twelve similar cases were collected from the European literature.

Two More Families with Cardiomegaly. M. Campbell and M. Turner-Warwick. Brit. Heart J. 18:393-402 (July) 1956 [London, England].

Two more families with cardiomegaly unassociated with any other familial disease are reported. The first family included a mother and her son, both with large hearts and bundle-branch block, who died at the early age of 29 and 23 years, respectively, one year and three years, respectively, after the onset of symptoms. In the second family, three members in three generations had large hearts and a slow heart rate. A young man and

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

maternal grandmother had a heart block and his mother had sinus bradycardia and bundle-branch block. The duration of symptoms in the grandmother was not known; in the mother they were manifested when she was 28 and still persisted 38 years later, but the son died suddenly at the age of 36 years, within five months of his first Stokes-Adams attack. The cases of the son and the mother in the second family show the extreme variability of survival times, but early and sudden death is more usual. Several other members of both families died at an early age or had a history of heart disease. Macroscopic and microscopic findings at autopsy in the two male patients are described. None of the accepted causes of cardiac enlargement was present. A diffuse degenerative process affecting the entire thickness of the myocardium appeared to be the fundamental lesion: the muscle fibers were hypertrophied, but the most striking feature was the vacuolation of muscle fibers and of the conducting system. Though familial cardiomegaly is generally unnoticed till early adult life, it seems more likely that there is a genetic cause; the evidence is scanty but suggestive of its inheritance as a dominant Mendelian character.

Psychiatric Manifestations of Cancer of the Pancreas. W. Karliner. New York J. Med. 56:2251-2252 (July 15) 1956 [New York].

Karliner presents the histories of three male patients, ranging in age from 55 to 64 years, who were referred for neuropsychiatric examination because of anxiety and depression, insomnia, anorexia, loss of weight, and abdominal pain radiating to the back. All three were found to have cancer of the pancreas. The author states that Savage and Noble reported four patients in whom cancer of the pancreas simulated psychogenic illness. The same authors reviewed 27 cases of verified carcinoma of the pancreas in which depression dominated the clinical picture. The physical findings in patients with cancer of the pancreas are negative or very inconclusive, except during the terminal stage of the disease. This makes diagnosis difficult during the early stages. Therefore the appearance of nervous or emotional symptoms associated with gastrointestinal pain that radiates to the back, without evidence of organic disease, should suggest the possibility of pancreatic disease. The cause of the neuropsychiatric manifestations of pancreatic cancer is unknown. The anxiety and depression presented by these patients is out of all proportion to the meager physical findings. Furthermore, the mental symptoms antedate the gastrointestinal complaints. Although there is no proof of a relationship between the mental symptoms and cancer of the pancreas, such a relationship may be more than coincidental.

Diabetes Insipidus and Pituitary Insufficiency. J. Warter, J. Schwartz and A. Aschmann. Presse méd. 64:1157-1158 (June 23) 1956 (In French) [Paris, France].

In 1954, West and co-workers reported results of hypophysectomy in 18 cases of cancer. In the nine cases in which diabetes insipidus had developed, it was revealed on postmortem examination that the hypophysectomy had not been total. Conversely, in the five cases where no polyuria was manifested, the removal of the hypophysis had been complete. Diabetes insipidus developed only in those cases in which the anterior pituitary had not been entirely removed. The authors observed the simultaneous presence of diabetes insipidus and a severe anterior pituitary insufficiency in a patient who had sustained a fracture of the base of the cranium in an automobile accident. After the accident polyuria of from 6 to 8 liters per day occurred. Evidence of diabetes insipidus was shown by Carter and Robins' test, as well as by Cates and Garrod's test, and the pituitary insufficiency was demonstrated as follows: fixation of radioactive iodine was not above 10.2% and the level of urinary 17-ketosteroids was 3.52 mg. Thyreostimuline and ACTH corrected these disturbances but did not increase the polyuria. Although diabetes insipidus never appears when the anterior lobe of the hypophysis has been entirely removed, it may develop when there is a minimal functioning of the anterior lobe of the hypophysis. When this threshold functioning is assured, diabetes insipidus immediately becomes completely evident clinically.

The Failure of Monosodium Glutamate in the Treatment of Hepatic Coma. I. R. Schwartz, E. Lehman, J. Hammond and others. Gastroenterology 30:869-881 (June) 1956 [Baltimore].

There have been contradictory reports about the value of the intravenous administration of monosodium glutamate in patients with cirrhosis of the liver and episodes of hepatic coma. Since January, 1954, Schwartz and associates have added the daily intravenous infusion of 20 gm. of monosodium glutamate to the usual regimen in the management of hepatic coma. The daily administration was continued until the patients either recovered or died. Although 22 patients were treated with monosodium glutamate, the diagnosis had been verified by either biopsy or autopsy in only 19. Thirteen of these 19 patients were in deep coma when treatment with monosodium glutamate was started, while in six patients treatment was initiated during impending coma. No appreciable effect on the state of coma or progressively fatal course could be observed in 17 of the 19 patients. A temporary recovery occurred in the first patient and an apparently complete recovery occurred in the second patient, but 18 of the 19 patients died. The recovery in one patient may have been the result of vigorous treatment of electrolyte disturbances rather than the concomitant use of monosodium glutamate. No apparent alteration in the progression into deep coma was noted in the six patients in whom the monosodium glutamate was given early. The authors reviewed recent investigations into the role of ammonia in hepatic coma. They conclude that evidence to date does not warrant implication of any single agent as a causative factor in hepatic coma.

Evaluation of a Four-Day ACTH Test in the Differential Diagnosis of Jaundice. T. C. Chalmers, R. J. Gill, T. P. Jernigan and others. Gastroenterology 30:894-899 (June) 1956 [Baltimore].

There have been several reports on the effectiveness of corticotropin (ACTH) and cortisone in lowering the serum bilirubin level of patients with jaundice due to intrahepatic disease. This effect has been suggested as a test for the differentiation of various types of jaundice. The authors describe a controlled study of the clinical value of this test in 41 patients. There were 18 patients with acute infectious hepatitis, 3 with chronic, and 2 with cholangiolitic hepatitis; there were 8 with cirrhosis, and 10 with extrahepatic obstructive jaundice. After a control period of three or four days the patients were given 40 units of ACTH gel every 12 hours for four days. This was followed by a post-treatment control period lasting three or four days. The interpretation of the test was based solely on the response of the total serum bilirubin to the administration of the ACTH. Blood specimens were collected daily while the patients were fasting. No specific patterns of response were observed, and the previously described usefulness of the test could not be confirmed.

SURGERY

Arterial Necrosis Following Resection of Coarctation of the Aorta. W. R. Benson and W. C. Sealy. Lab. Invest. 5:359-376 (July-Aug.) 1956 [Philadelphia].

The authors describe clinical and pathological studies on two patients in whom arterial necrosis developed after resection of a coarctation of the aorta. The first patient was a 22-year-old man. Two weeks before death the area of coarctation was resected. The procedure required eight hours, during which the patient's condition remained good. The coarctation was 1.5 cm. below the aortic arch and produced almost complete obstruction. The collateral arteries were greatly enlarged. On the ninth postoperative day (four days before death), the abdomen was distended. He vomited, producing a cupful of bloody material. Exploratory laparotomy revealed infarction of most of the small intestine and the proximal portion of the colon. During the final stages of removal of the intestine, cardiac arrest occurred. Despite cardiac massage, defibrillation, and intracardiac administration of epinephrine, the heart did not resume its beating. Autopsy revealed double coarctation of the aorta; a bicuspid aortic valve; left ventricular dilatation and hypertrophy; hypoplasia of the major branches of the aorta below the coarctation; necrosis of the media of the arteries and arterioles of the intercostal spaces, of the abdominal viscera, and of the muscles of the anterior abdominal wall; infarctions of the intestines, adrenals, liver, and kidneys; hemorrhages in the stomach, pancreas, and kidney pelves, congestion of the liver with necrosis of the paracentral cells; pulmonary atelectasis; and diffuse fine myocardial fibrosis.

The second patient, a 4-year-old boy, was subjected to resection of the area of coarctation and ligation of the patent ductus arteriosus. Collateral circulation was extensive, and many vessels were the size of those commonly seen in adults with aortic coarctation. The coarctation was just below the aortic arch and the point of entrance of the patent ductus. It formed a complete obstruction. An end-to-end anastomosis was performed. The period of anesthesia was five hours. On the third and fourth postoperative days, the patient complained of vague abdominal pain. On the 16th postoperative day, abdominal pain was more severe and localized in the right lower quadrant. An exploratory laparotomy was performed, and 24 in. of gangrenous terminal ileum was removed. The pain was relieved after the operation. Two months later the boy seemed well. Examination of the surgical specimen revealed that the intestinal segment was irregularly ulcerated throughout most of its 70 cm. These ulcerations sometimes extended into the muscularis. The intestinal arteries and arterioles were essentially similar to those in the first patient. The areas of necrosis were principally in the media and progressed from an alteration of staining qualities of cells to intensely staining fibrinoid degeneration. Necroses in the larger vessels were characterized by an acellular hyaline change in which the muscle cells and nuclei failed to stain. Little or no inflammatory reaction accompanied these changes. The smaller arteries had an intense fibrinoid necrosis, predominantly of the media but frequently involving the entire arterial wall. The lesions are believed to be primarily the result of changes in the circulatory dynamics after operation. Three cases reported previously are similar in many respects to the two described here. The authors conclude that, although this complication is infrequent, its presence should be suspected whenever acute abdominal symptoms develop after aortal resection.

Structural Alterations in Human Aortic Homografts One to Two and One-Half Years After Transplantation. O. Creech Jr., M. E. DeBakey, D. A. Cooley and B. Halpert. Surg. Gynec. & Obst. 103:147-154 (Aug.) 1956 [Chicago].

The four patients whose histories are presented survived 14, 24, 28, and 30 months respectively after aortic aneurysms had been excised and replaced by refrigerated homografts. Gross and microscopic studies on these implanted aortic homografts confirmed observations previously made on human aortic homografts. Such a homograft becomes functionally and structurally adapted to its new environment and retains much of its structural pattern while it is being reinforced by the fibrous connective tissue of the host. Alterations observed in the grafts 14, 24, and 28 months old were not present in the graft 30 months after transplantation. The difference was apparently due to the fact that the younger grafts were long, while the oldest was short and did not include the bifurcation. The ultimate fate of aortic homografts is as yet not known. In the meantime, this procedure is an effective means of treating a variety of lesions of the aorta, and on the basis of experience to date the aortic homograft can be utilized with confidence.

Acute Pseudomembranous Enterocolitis in the Postoperative Patient. R. E. Weismann and E. B. Twitchell. Ann. Surg 144: 32-38 (July) 1956 [Philadelphia].

The pathological characteristics of pseudomembranous enterocolitis consist of inflammatory changes in the gastrointestinal tract, most commonly in the large and small intestine but occasionally in the stomach, with the formation of a pseudomembrane on the mucosal surface. The initial changes are vascular engorgement in the mucosa and submucosa, progressing to edema and perivascular hemorrhages. Either mild or acute cases may complicate any postoperative convalescence. It has been observed more commonly after major surgical procedures on the gastrointestinal tract. In the authors' patients the onset was with fever, chills, choleriform diarrhea, abdominal distention, and vomiting In several of the severe cases clinical dehydration was seen before any other indication of change appeared; the mouth would be dry and the face drawn in spite of adequate fluid intake and renal output.

In earlier literature this disease is described as running a fulminating and usually a fatal course. Some authors have identified it with the Staphylococcus aureus (Micrococcus pyogenes) It should be stated that the staphylococcic enteritis of food poisoning or other source is a distinctly separate morphological entity Pseudomembranous enterocolitis can no longer be regarded as rare. It carries a mortality that can be reduced by prompt clinical therapy. The predominant organism found in five antemortem stool specimens was Staph. aureus, resistant to penicillin, streptomycin, aureomycin, and terramycin, but sensitive to chloramphenicol and in two instances to erythromycin. The disappearance of the erythromycin-sensitive Staph. aureus from the stool after erythromycin treatment has been reported to coincide with clinical improvement. Corticotropin (ACTH) and cortisone have been said to be beneficial. Both mild and severe forms of pseudomembranous enterocolitis appeared in the authors' cases and was fatal in 73% of the severe cases. The fulminating circulatory collapse in the severe form demands immediate diagnosis and aggressive supportive therapy if a fatal outcome is to be avoided In the milder form of the disease the onset is often subtle and the diagnosis must be made on the basis of signs of toxicity and disturbed gastrointestinal function. Specific therapy will usually prevent a serious outcome in mild forms.

Vacuolated Cells in the Sputum Simulating Adenocarcinoma Cells. F. R. Philps. Brit. J. Cancer 10:24-25 (March) 1956 [London, England].

Fragments of tissue containing vacuolated cells are frequently seen in carcinoma, and, though the cells composing the clump usually show other characteristics of malignancy, there are occasions when clumps of vacuolated cells of relatively normal appearance are exfoliated into the sputum from carcinomas Until 1954 the author had never seen such vacuolated cells except in patients with carcinoma, but during the past year he found them in two patients without evidence of malignancy. One of these patients had had asthma as long as he could remember and recently had felt pain in the right side of the chest Specimens of sputum were examined and one was found to contain a clump of vacuolated cells. This was thought to be due to carcinoma. Bronchoscopy revealed no abnormality, but the radiological evidence suggested a peripheral carcinoma in the right lung and thoracotomy was performed. The lung was indurated and a biopsy was taken. Microscopic examination of the biopsy specimen revealed no evidence of malignancy, however, many of the cells comprising the bronchiolar lining showed vacuolation, and it is assumed that the fragment in the sputum originated from this tissue.

Appraisal of Adenomatous Polyps of the Colon, Their Histopathology and Surgical Management. H. E. Bacon and A. R. Peale. Ann. Surg. 144:9-18 (July) 1956 [Philadelphia].

Adenomatous polyps or polypoid adenomas are tumors notorious for their unequivocally premalignant character. The study deals with those that are located between the cecum and the rectosigmoid junction. They are variable in size and may be solitary or multiple. According to Laurens and to MacElwa they may be grouped as follows: (1) benign adenoma, which a uniform proliferation of glands regular in size and shape; (2) adenoma with atypism or polyps with certain localized alterations in cellular characteristics that have not yet reached the stage where they may be called frankly malignant; (3) adenoma malignum or adenocarcinoma in situ, a type of lesion with accepted cytological features of malignant neoplasia, better described as adenoma with adenocarcinomatous change, the adenocarcinomatous change being in situ; and (4) adenocarcinoma with definite invasion of the muscularia mucosa. Diagnosis and surgical treatment are effective when the lesion is discovered and eradicated before invasive malignancy has occurred. In 202 patients the tumor was demonstrated radiologically or sigmoidoscopically, or by coloscopy after one or more bowel incisions had been made. Multiplicity of polyps was noted in 33% of the patients. In 200 cases the adenomatous polyp was removed by a transcolonic approach. A solitary adenomatous polyp of the colon with a substantial stalk is treated by colotomy or polypectomy; an adenomatous polyp with a long thin stalk showing atypical changes or carcinoma in situ is also treated by colotomy or polypectomy; an adenomatous polyp that is sessile is removed by segmental resection; a mammillation or minute adenoma, or both, is destroyed by fulguration through the endoscope. The mortality associated with resection was four times as great as that with polypectomy in this series; polypectomy, then, when used according to clinical judgment and the pathological observations, has a definite place in the treatment of lesions that may well be regarded as premalignant tumors.

The Treatment of Selected Cases of Multiple Polyps, Familial Polyposis, and Diverticular Disease of the Colon by Subtotal Colectomy and Ileoproctostomy. I. Teicher and J. I. Abrahams. Surg. Gynec. & Obst. 103:136-146 (Aug.) 1956 [Chicago].

The authors describe observations on five patients with multiple polyps of the colon, two with familial polyposis, and one with diverticulosis of the colon and massive hemorrhage. All eight patients were treated by subtotal colectomy and ileoproctostomy, which usually results in the preservation of a normal state of nutrition and little or no abnormality in the intestinal function. The authors feel that this should encourage a wider utilization of the operation in the treatment of a variety of benign and malignant lesions of the colon. Subtotal colectomy and ileoproctostomy is the most effective treatment of multiple polyps of the colon, because this procedure removes not only the polyps that have been detected but also hidden polyps. If carcinoma is found in any of the polyps in the resected specimen, the patient is already protected by an adequately radical resection of the colon. Selected patients with familial polyposis of the colon may be managed by subtotal colectomy and ileoproctostomy, but in approximately 5% of these patients cancer will develop in the retained rectal segment. This risk is the price that must be paid for retaining normal intestinal function in preference to an ileostomy. The two patients with familial polyposis presented here both refused ileostomy in favor of ileoproctostomy, because the latter procedure afforded them essentially normal intestinal function. Both are intelligent and realize the necessity of continued follow-up examinations at intervals of three months. They understand the danger of the malignant degeneration of a polyp in the rectal pouch. Some complications of diverticular disease of the colon can be most adequately treated by subtotal colectomy and ileoproctostomy. The operation removes all areas of disease and has no crippling effect on the gastrointestinal function.

Thrombocytopenia and Hemorrhage in Hemolytic Blood Transfusion Reactions. P. W. Pifer, M. A. Block and C. P. Hodgkinson. Surg. Gynec. & Obst. 103:129-135 (Aug.) 1956 [Chicago].

If a hemolytic blood transfusion reaction occurs at the time a patient is undergoing surgery, bleeding from the wound and from all cut surfaces is almost uncontrollable. The authors studied some of the coagulation factors during experimentally produced hemolytic blood transfusion reactions. They produced hemolysis by the intravenous injection of fresh rabbit blood into dogs. They found that the intravenous administration of heterologous blood results in an abnormal bleeding tendency similar to that observed in hemolytic blood transfusion reactions in man. A critical precipitous fall of blood platelets was associated with the hemolytic transfusion reaction. The plasma fibrinogen also decreased slightly. The bleeding time was usually prolonged, and frequently the coagulation time was also prolonged. The prothrombin time remained normal throughout all experiments. Blood hemoglobin usually fell after the infusion of heterologous blood. These changes were generally observable for several hours, but normal values had usually returned 24 hours after the infusion of heterologous blood.

In an effort to neutralize the effect of any heparin-like substance that might have produced the bleeding tendency, 100 mg. of protamine sulfate was given intravenously to some of the dogs that had received heterologous blood, but this did not significantly change the abnormalities that resulted from the administration of the heterologous blood. The depression in the blood platelets appeared to be of major importance in the etiology of the bleeding tendency observed in the experiments. Whether platelet depression is the primary reason for the bleeding tendency associated with incompatible blood transfusions in man is unknown. It appears that fibrin and platelet emboli or thrombi form in the blood vessels throughout the body as a nonspecific reaction in a number of conditions in which foreign proteins are present in the blood stream. This condition then results in thrombocytopenia and hypofibrinogenemia and a bleeding tendency. Either thrombocytopenia or hypofibrinogenemia may predominate in varying situations.

Sweat Gland Carcinoma. G. B. Elliott and D. W. Ramsay. Ann. Surg. 144:99-106 (July) 1956 [Philadelphia].

Sweat gland carcinomas are tumors of the sweat glands or sweat gland adenomas and fall into two well-defined groups, almost equal in size. In one group a quiescent nodule in the dermis draws attention to itself by aggressive growth and fixation to the overlying skin, which becomes purplish-red in color; metastasis takes place into regional nodes. The second group is characterized by a progressive intractable weeping eczema of the skin. Histologically the two groups show many characteristics in common. The majority of the carcinomas in the first group arise in the axillas or the anogenital skin, though some have occurred in the scalp, in Moll's gland of the eyelid, and in the upper milk line, including the areola, of the breast. In many cases the skin blemish is known to be preceded by a painless movable discrete dermal nodule, quiescent for many years. A surgically treated case of axillary gland carcinoma of apocrine type with node metastases is reported in a 64-year-old man. In many cases malignancy is believed to have supervened on a preexisting papillary syringocystadenoma. Allen has pointed out that well-differentiated epitheliomas and even melanocarcinomas have been erroneously identified as apocrine sweat gland carcinomas.

The second group of sweat gland carcinomas are instances of extramammary Paget's disease. They are characterized by large ovoid cells with clear cytoplasm scattered through otherwise normal skin, and they secrete a watery ooze. The clinical and pathological characteristics of the main variants of sweat gland carcinomas seem to have a close relationship to the behavior of mammary carcinoma.

NEUROLOGY & PSYCHIATRY

Neurologic Manifestations of Tumors of the Glomus Jugulare: Chemodectoma, Nonchromaffin Paraganglioma or Carotid-Body-like Tumor. R. G. Siekert. A. M. A. Arch. Neurol. & Psychiat. 76:1-13 (July) 1956 [Chicago].

The tissue comprising the glomus jugulare lies in the adventitia of the dome of the jugular bulb as well as within the temporal bone. Because of its position, tumors arising in the glomus jugulare may produce neurological symptoms and signs. The author discusses the neurological manifestations observed in 33 patients in whom the diagnosis of tumor of the glomus jugulare was made microscopically, either at biopsy of a polyp or mass in the ear or from tissue removed at mastoidectomy or some other operative procedure in the region. Tumors of the carotid body were not included in the study. The site of origin of glomus tumors was assumed to be any one (or several) of the glomic formations comprising the glomus jugulare complex. The tumor presented in several ways: as a polyp easily visible in the external auditory canal, reddish or bluish-red, often pulsating; as a polypoid growth behind the eardrum or reddening and obscuring the landmarks of the drum; or as a red, friable mass with the appearance of granulation tissue in the external canal. In four patients a tumor was seen within the cavity left after radical mastoidectomy. Growths of this type bleed easily, and occasionally, when they are removed by simple polypectomy, brisk hemorrhage may occur.

Twenty-two of the 33 patients were women. The ages of the patients at the time the diagnosis was made ranged from 33 to 71 years. The ages when symptoms began ranged from 2 to 65 years; however, only one patient began having symptoms before 20 years of age, and this one had an extraordinarily long history, of 42 years, of chronic purulent aural discharge. The duration of symptoms before the diagnosis was established averaged seven years. Involvement of the acoustic nerve was observed in 27 of the 33 patients. In 14 of the patients other cranial nerves in addition to the eighth cranial nerve were involved. The neurological symptoms included deafness, tinnitus, vertigo, hoarseness, dysphagia, facial weakness, diplopia, and pain in the ear, head, or face. Involvement of the cranial nerves, from the 3rd through the 12th, except for the 4th, were observed, and bruit, ataxia, nystagmus, Horner's syndrome, and exophthalmos were present.

Pathogenesis of Experimental Poliomyelitis: I. The Virus Content of the Cerebrospinal Fluid. G. Kersting, H. Lennartz and H. Pette. Deutsche Ztschr. Nervenh. 175:72-86 (No. 1) 1956 (In German) [Berlin, Germany].

Opinions are still divided as to whether the virus of poliomyelitis spreads by way of the bloodstream or along the nerves. The authors report studies on 18 African monkeys, 6 of which were given intraneural injections of a suspension of the Brunhilde strain of the poliomyelitis virus, 6 others were given intramuscular injections of the same suspension, and the 6 remaining animals were given 5 ml. of a concentrated suspension in 100 cc. of banana pulp by mouth. This oral administration of the virus never resulted in the development of poliomyelitis, nor was it possible to detect the virus in either the blood or the cerebrospinal fluid. This seems to prove that these African monkeys are not susceptible to the oral administration of poliomyelitis virus. Three monkeys were given the injection into the sciatic and three into the ulnar nerve. The injection into the sciatic nerve was followed by symptoms of typical paralytic poliomyelitis after an incubation period of from 5 to 10 days, and the disease caused death after an illness of two or three days. Viremia was present approximately four days before the appearance of the neurological symptoms. By the time the paralytic symptoms appeared the virus had usually disappeared from the blood stream, but it was found in the cerebrospinal fluid two days after the onset of the viremia and it was generally still present there at the onset of the paralysis. The three animals receiving the virus by injection into the ulnar nerve also showed typical poliomyelitis symptoms. Viremia was always present from five to two days before the appearance of the clinical symptoms, but in these animals the virus was never found in the cerebrospinal fluid.

The intramuscular inoculation of the virus was given to three monkeys in the left upper arm and to the other three in the right thigh. Poliomyelitic paralysis developed in two of the animals receiving the inoculation into the arm. Viremia was observed in these two animals as well as in the third, which did not develop symptoms. In the animals that showed paralytic symptoms, the virus was also found in the cerebrospinal fluid at the time of onset of the paralytic symptoms. Only one of the three monkeys in which the virus was injected into the thigh showed symptoms of poliomyelitis, and in this animal virus was found in the blood as well as in the cerebrospinal fluid. In the two animals who remained healthy, poliomyelitis virus was found in neither the blood nor the cerebrospinal fluid. None of the observations described suggest that the virus of poliomyelitis travels along the nerves. The fact that no involvement of the central nervous system occurred without a previous viremia, the chronologic relationship between the appearance of the virus in the blood and in the cerebrospinal fluid, and the onset of paralysis indicate that the virus reaches the central nervous system by way of the blood stream. The authors believe that the relatively constant time difference between the appearance of the virus in the cerebrospinal fluid and the onset of paralytic symptoms does not indicate that the central nervous tissues are infected by way of the cerebrospinal fluid. On the contrary, they think that the cerebrospinal fluid and the tissues of the brain and the spinal medulla receive the virus simultaneously through the bloodstream. The span of time during which there are no symptoms seems to be necessary for the development of the disease process to the point at which the first signs of paralysis indicate that the damage to the motor nerve cells has reached a certain quantitative level.

THERAPEUTICS

Radioactive Iodine in Treatment of Hyperthyroidism: Preliminary Report on Results. L. Fierro del Rio and L. Cancino Serna. Rev. invest. clin. 8:21-36 (Jan.-March) 1956 (In Spanish) [Mexico, D. F., Mexico].

Thirty-eight patients with hyperthyroidism were observed There were 30 women and 8 men, between the ages of 12 and 68 years. Thirty-four patients had a diffuse toxic goiter and four had a toxic thyroid adenoma. The treatment consisted of oral administration of radioactive iodine (I^{131}). The drug was given in a dose of 1 mc. per gram of weight of thyroid tissue, as calculated by palpation of the thyroid gland. Dosage for patients with diffuse toxic goiter who received a single dose varied betwee 2.5 and 13.2 mc.; those receiving two doses had a total amoun of from 6.9 to 12.2 mg.; and two who received three doses had total amount of 14.1 and 17.5 mc. respectively. The single dos for patients with toxic thyroid adenoma was 8, 10, 13.6 and 15 mc. respectively. Thirty-five patients were followed up for tw and a half years. All patients were cured. One patient with tox thyroid adenoma and cardiac complications of rheumatic feve recovered from both conditions. Later she developed hypothyroidism that is controlled by daily small doses of desiccated thyroid (16 mg.). Administration of I^{131} is the treatment of choice in diffuse toxic goiter and in toxic thyroid adenoma The only contraindications are pregnancy and lactation. Hypothyroidism may occur. It is either transient or controllable by administration of daily small doses of desiccated thyroid. The treatment is economical and well tolerated. It does not cause complications Great improvement appears within two weeks after the treatment and complete cure in four months. However, it does not correct exophthalmos.

Clinical Investigations with the New Sedative, (Nonbarbiturate) Doriden. W. Niessen. München. med. Wchnschr. 98:844-845 (June 15) 1956 (In German) [Munich, Germany].

The new sleep-inducing drug, Glutethimide (Doriden), is alpha-ethyl-alpha-phenyl-glutarimide; it is not a barbiturate The author studied its efficacy on 194 patients, after 122 others had been eliminated from the trial by a double placebo test because of excessive suggestibility. Preliminary placebo tests are of great importance in evaluating sleep-inducing drugs, as psychological factors and suggestibility play an important part in many patients who take hypnotics. The author regards as normal a type of sleep in which fairly rapid going to sleep is followed by three or four hours of deep, sound sleep and this by a further three or four hours of less profound sleep that merges gradually into the waking state. One hundred fourteen of the 194 patients attained normal sleep after taking an adequate dose of Glutethimide varying individually from 1 to 2 tablets. Those who did not respond to 2 tablets also usually failed to respond to 3 tablets. The author concludes that Glutethimide safely counteracts moderate and severe insomnia. It can be used over long periods without the danger of side-effects or other sequels, the drug does not influence the blood pressure, the blood picture, or the function of the liver.

Tetracycline with Special Regard to Possibility of Development of Staphylococcus Enteritis. K. R. Eriksen, E. H. Thaysen and F. Raaschou. Ugesk. læger 118:543-547 (May 24) 1956 (In Danish) [Copenhagen, Denmark].

In connection with cases reported in the literature and two of the authors' cases, attention is called to the fact that administration of tetracycline, as of chlortetracycline (Aureomycin) and oxytetracycline (Terramycin), involves the risk of the development of staphylococcous enteritis. Staphylococcous enteritis ocurs so seldom and so capriciously that it is not possible to determine from the clinical material whether the frequency of the complication is the same after administration of the three antibiotics. McCorry and Weaver conclude that, while the incidence of diarrhea is the same after use of all three antibiotics, nausea manifests itself less often after use of tetracycline, which agrees with the general conception that the diarrhea depends on changes in the intestinal flora, while the cause of the nausea lies in the chemical structure of the substances. Tetracycline will perhaps prove more advantageous than Aureomycin and Terramycin with regard to the complication of nausea; as for the intestinal complications, including the risk of staphylococcous enteritis, the three tetracyclines will probably prove to be equally responsible.

Treatment of Typhoid with Isoniazid. G. Conese and L. Colonna. Policlinico (sez. med.) 63:137-148 (June) 1956 (In Italian) [Rome, Italy].

The authors studied the effect of isoniazid on 41 patients with typhoid. Twenty-three patients were treated only with isoniazid. Two hundred milligrams was the maximal dose per day; it was given in divided doses of 50 mg. Treatment was continued for a few days after disappearance of the fever. Eighteen patients were treated with 200 mg. per day of isoniazid and 1.5 gm. per day of chloramphenicol. Most of the patients were young. Clinical results were very satisfactory. Splenomegaly and hepatomegaly were the last symptoms to disappear. Recurrence of the fever was noticed in only one patient. The limited number of cases does not permit the authors to formulate a hypothesis on the mechanism of action of the drug. The effect of isoniazid depends on the stage of the disease; poor results are obtained in the acute stage. Isoniazid was chosen on account of its effect on the diencephalon-pituitary system. The synergistic action of chloramphenicol failed in only one patient.

Bacteroides in Intra-Abdominal Sepsis: Their Sensitivity to Antibiotics. W. A. Gillespie and J. Buy. Lancet 1:1039-1041 (June 30) 1956 [London, England].

Peritonitis is usually caused by organisms from the intestine. Escherichia coli and other members of the coliform group and aerobic streptococci are usually incriminated. Anaerobic streptococci and clostridia are sometimes mentioned, but the anaerobic nonsporing bacilli of the Bacteroides group are usually ignored. The authors made studies on the bacteriology of intra-abdominal sepsis to find out how often Bacteroides were present as compared with other organisms and to determine the sensitivity of Bacteroides to antibiotics and sulfonamide. They regarded all gram-negative anaerobic nonsporing bacilli as Bacteroides, although this definition covers a heterogeneous group of organisms. Most of the organisms were isolated from the pus of suppurative lesions in the abdomen. There were 34 specimens from either localized or generalized peritonitis caused by appendicitis, 18 specimens from peritonitis of other causes, and 46 swabs from discharging wounds of the abdominal wall. In addition, 13 acutely inflamed appendixes were obtained from the operating theater as soon as possible after operation.

The organisms most commonly identified in the 111 specimens examined were Bacteroides in 67 specimens, coliform organisms in 66, anaerobic streptococci in 43, and aerobic streptococci in 40. The cultures of exudates on the surfaces of inflamed appendixes yielded relatively more anaerobic streptococci and Bacteroides than did the cultures of peritoneal pus. This difference probably reflects the greater care with which cultures from the appendixes were studied. The cultures were nearly always mixed, but in many specimens Bacteroides were the predominating organisms and often they were numerous. Most of the Bacteroides strains were resistant to penicillin, streptomycin, bactitracin, neomycin, and polymyxin B. All were sensitive to the tetracyclines and to chloramphenicol. Most were sensitive to sulfonamide and moderately or fully sensitive to erythromycin. The authors feel that it would be wrong to dogmatize about the antibiotic treatment of a condition whose bacterial causation is as complex and variable as peritonitis. Penicilin and streptomycin are often given simultaneously to control infection by gram-positive organisms and by coliform bacilli. The sensitivity tests showed the tetracyclines to be highly active against Bacteroides; they are also active against most coliform bacilli, streptococci, and clostridia. The tetracyclines are therefore probably superior to penicillin and streptomycin, which are unlikely to influence abdominal infections in which Bacteroides are the main agents. Those who prefer to use penicillin and streptomycin in peritonitis should be prepared to substitute a tetracycline if these drugs prove ineffective.

The Effect of Beta Sitosterol on the Serum Lipids of Young Men with Arteriosclerotic Heart Disease. J. W. Farquhar, R. E. Smith and M. E. Dempsey. Circulation 14:77-82 (July) 1956 [New York].

Previous studies in human beings on unrestricted diets indicated that the plant sterols (beta or gamma sitosterol) reduce the serum cholesterol level. This report is concerned with observations on 15 young men, ranging in age from 26 to 45, who had had myocardial infarction. Serial serum lipid determinations were made during a three-phase study: (1) a premedication period of 6 to 12 weeks, (2) a period of sitosterol administration of 12 to 24 weeks, and (3) a period of placebo administration of 10 to 16 weeks. Cholesterol intake was from 200 to 300 mg. per day in the nine patients on fat-restricted diets and 900 to 1,000 mg. per day in the six patients on diets "normal" in fat content. Three equal portions of β-sitosterol were given orally immediately before meals in total amounts of 12 to 18 gm. per day. For comparative base-line studies, serum lipid determinations were made on 15 apparently normal men matched with the patients as regards age. It was found that the patients had significantly increased cholesterol, beta lipoprotein lipid, and total lipid levels. The administration of β-sitosterol resulted in highly significant reductions in serum cholesterol and β-lipoprotein lipid levels, with a lesser reduction in total lipid and a slight rise in α-lipoprotein lipid. The apparent lack of deleterious effects, coupled with the observed changes, suggests the potential benefits of sitosterol administration. Its role as a therapeutic agent in clinical medicine has not yet been established.

Researches on a New Hypoglycemic Substance, the N-1-Sulfanilyl-N-2-n-Butylcarboamide: Part I. S. Garattini and L. Tessari. Clin. terap. 10:418-422 (April) 1956 (In Italian) [Rome, Italy].

N-1-sulfanilyl-N-2-n-butylcarboamide is a bacteriostatic substance with a hypoglycemic effect in the normal animal and in animals with diabetes. The effect is proportional to the quantity of substance received by the animal. The authors report on the distribution of the drug in the organism and the sensitivity to insulin in rats treated for a long time with the drug. Distribution of the drug in the organism is compared with the distribution of a regular sulfamide. Albino rats averaging 150 gm. in weight were given quantities of the drug equal to -00 mg. per kilogram of sulfamide and 315 mg. per kilogram of N-1-sulfanilyl-N-2-n-butylcarboamide. The drug was absorbed readily; the elimination was slower than the elimination of simple sulfamides. The drug had no particular tropic effect on the pancreas. It had poor penetrability for the nervous tissue.

Sensitivity to insulin was studied in rats treated for nine consecutive days with 750 mg. per kilogram of the new sulfamide by gastric test. Twenty-four hours after the last dose of the drug and after 20 hours of fasting, the rats were injected with insulin. Rats treated with the drug were more sensitive to the effect of insulin than control rats. This effect was not due to a combined effect of the insulin and the new sulfamide. The new sulfamide causes a 35% fall in glycemia and increases the effect of the hepatic glycogen. Glucose given to rats that had received the new sulfamide and insulin had no effect.

Latin American Malaria Control Programs • •
Chamber of Commerce Survey on Health Benefits • •
$2,000,000 Granted for Rehabilitation Financing • •
Food Irradiation Reactor for Food Preservation • •
Statute of International Atomic Energy Agency • •

CONTROL OF MALARIA

The United States is planning to contribute an extra $1,500,000 to the Pan American Sanitary Bureau to help in next year's malaria control programs in various Latin American countries. This is in addition to the U. S. regular contribution to the agency, which this year is $1,386,000. The latter figure represents two-thirds of the agency's total budget of $2,200,000 for 1956. The special contribution was announced by Dr. Henry van Zile Hyde, U. S. representative to the directing council of the policy-making Pan American Sanitary Organization. Dr. Hyde also is chief of the division of international health in the Public Health Service. The delegates at this meeting approved a $2,400,000 budget for the bureau's operations in 1957. In submitting his request for funds for next year, Dr. Fred L. Soper, director of the bureau, stressed the need to concentrate on eradication programs against malaria, smallpox, yaws, and the Aedes aegypti mosquito, which is the urban vector of yellow fever.

The bureau's 1957 program includes some 126 health projects, in which the agency collaborates with health administrators of member governments. It also plans to set aside $155,480 for fellowship training for public health administrators. This program is designed to help national health administrations strengthen their own services so that they will gradually require less international assistance. In addition to the projected $2,400,000, an estimated $1,402,970 allocation has been made by the World Health Organization and another 1 million dollars from the United Nations technical assistance funds.

HEALTH INSURANCE BENEFITS

A U. S. Chamber of Commerce survey of 1,000 business firms shows that health insurance and other fringe benefit costs averaged $819 per employee in 1955, an increase of $99 since 1953. Fringe benefits were listed as payments by employers for pensions, vacations, social security, and insurance, including health insurance. Benefit payments varied widely among the reporting companies, ranging from less than 5% to over 50% of payroll. The $819 average was broken down as follows: $254 for programs of pensions and insurance, $254 for vacations and holidays, $145 for legally required programs such as old age and survivors insurance and unemployment and workmen's compensation, $89 for rest periods, and $77 for miscellaneous.

Dr. Emerson P. Schmidt, director of the chamber's economic research department, noted that weekly wages and hourly rate are no longer accurate measure of either worker income or the labor costs of doing business. "During recent years, pensions, social security and a host of other benefits have substantially increased both the well-being of employees and the cost of going business," the Chamber report says. "Vacations, holidays, rest periods and other payments for time not worked have given workers increased compensation for each hour actually on the job. They have at the same time increased the employer's cost for each hour of productive labor."

REHABILITATION FINANCING

During the fiscal year ending last June 30, the federal government made more than 2 million dollars available to schools and individuals to train professional workers to help restore handicapped persons to useful employment. Of the total, a little more than a million dollars went for 154 teaching grants, the remainder into traineeships to more than 2,000 students. Educational institutions in 31 states shared in the teaching grants, which are designed to help pay the cost of establishing or expanding training courses in professional rehabilitation fields. Grants were made in such fields as medicine, rehabilitation counseling, social work, nursing, occupational therapy, physical therapy, and work with the blind. Of the $1,729,942 in grants for basic professional training, $667,866 went for rehabilitation counseling, $387,262 for medical training; and $674,814 for such courses as nursing, physical therapy, occupational therapy, and social work.

FOOD PRESERVATION

Eleven companies have offered to participate in the design, development, and construction of a food irradiation reactor for use in the food preservation program of the Army Quartermaster Corps, a project in which hospitals also are interested. The Atomic Energy Commission says the site for the new Army Ionizing Radiation Center will be selected soon by the Army, on the basis of recommendations of a joint Department of Defense—AEC committee.

The reactor will provide an intense source of gamma radiation for use in food irradiation and preservation and in experiments with other materials. It will be water-moderated and will be fueled with solid fuel elements. For several years Army and AEC researchers have been experimenting with the preservation of certain types of food through irradiation, a process that it is hoped will replace canning and freezing in the preservation of some foods.

ATOMIC ENERGY RESEARCH

International cooperation for development of peaceful uses of atomic energy should, in the opinion of chairman Lewis L. Strauss of the U. S. Atomic Energy Commission, "increase man's knowledge of his own body and that of the plants and animals that nourish

Tuckahoe, New York

Washington News—Continued

him, and of the pests which threaten him, to the end that the art of healing will advance and new ways be found to increase the food supply of the world." Admiral Strauss added that one effect of the adoption of the statute should be "prolonging man's span of useful life." The AEC head made his remarks in an address to the international conference on the Statute of the International Atomic Energy Agency. He said the statute, banding together the nations of the world for peaceful atomic energy research, also should: (1) accelerate the application of the peaceful uses of atomic energy everywhere, and at the same time "divert important amounts of fissionable material from atomic bomb arsenals." (2) stimulate the discovery of new fundamental data "on which all progress depends," and (3) encourage young and imaginative minds in many countries to seek careers in the new disciplines of nuclear science and engineering "to the end that they may improve the economy and health of their homelands."

The conference, held at United Nations in New York, was described as the largest gathering of nations to be held since the end of World War II. It was an outgrowth of President Eisenhower's proposal to United Nations for a worldwide organization for development of peaceful uses for atomic energy.

RESEARCH FUNDS

U. S. Atomic Energy Commission announces award of 48 research contracts in the life sciences, including 18 in medicine for which more than $350,000 was distributed. All contracts are for one year. Of the awards in medicine, 13 are for continuation of projects, and 5 for new projects. Largest of the new contracts in medicine is for $14,595 to New York University-Bellevue Medical Center for a study of tissue reactions to interpulmonary radiation. The second largest is to the Yale University School of Medicine ($12,900) for an investigation of rapid freezing of bone marrow and spleen and their radioprotective value. Other schools receiving new AEC grants are the University of Minnesota ($8,700), Research Foundation of the State University of New York ($7,553), and University of Michigan ($8,846).

Largest renewal grant was $75,853, to Harvard University for a continuation of studies on various uses for radioisotopes. Second largest was $50,000. to Parke, Davis and Company to continue a study of animals exposed to total body irradiation with gamma rays. Other renewal grants went to the following institutions: Columbia ($18,000), Georgetown ($1,600), George Washington ($13,455), Harvard (two additional grants of $11,463 and $24,379), Iowa State ($10,800), Massachusetts Eye and Ear Infirmary ($12,839), Massachusetts Memorial Hospitals ($30,000), Montefiore Hospital ($25,000), and New York University-Bellevue (two grants of $28,898 and $11,800).

INDIAN HEALTH

The Advisory Committee on Indian Health, meeting in late September in Washington, reviewed a comprehensive survey that had been made of Indian health problems. Some time in October the advisory committee will transmit results of the survey to co gressional committees, which earlier in the year requested that it be made. The nine-man committee includes four physicians from various public health fields, and five leaders in other professions. Three of the latter are themselves Indians.

The committee was organized to assist the U. S. Public Health Service in its efforts to improve and expand the medical care and health services for some 350,000 Indians, Aleuts, and Eskimos.

PERSONNEL

Lieut. Col. William H. Crosby, chief of the department of hematology, Walter Reed Army Institute of Research, has been decorated with the Cuban National Order or Merit. Colonel Crosby is the second American Medical Corps officer to be made a member of this national order. . . . Bernard M. Anderman has been appointed chief of audiology and speech correction in the Veterans Administration department of medicine and surgery at Washington, D. C. He succeeds Dr. Kenneth O. Johnson, who left the VA to become director of the San Francisco Hearing and Speech Center. Dr. Anderman, formerly chief audiologist of the VA regional office in New York City, will devote much of his time to the current VA program for the reassessment of hearing impairment. . . . Dr. William L. Benedict, executive secretary-treasurer of the American Academy of Ophthalmology and Otolaryngology, has been named a member of the Public Health Service National Advisory Council on Neurological Diseases and Blindness. . . . Paul M. Hawkins of Washington, D. C., has been appointed counsel on the staff of the Health Insurance Association of America. . . . George D. Frye is the new chief of occupational therapy in the physical medicine and rehabilitation service of the department of medicine and surgery at the VA Central Office in Washington, D. C. He was formerly chief of occupational therapy at the VA hospital in Knoxville, Iowa.

MISCELLANY

Armed Forces and civilian urologists met at Walter Reed Army Medical Center, Washington, D. C., for the fourth annual James C. Kimbrough Urological Seminar. Col. James C. Kimbrough, in whose honor the seminar was named was chief of the urology service at Walter Reed from 1946 until his retirement in 1953. He died last August. . . . The Veterans Administration announces that more than 95% of the 572,800 compensation and pension claims of veterans that have undergone a review were accurate and required no adjustment. This review, covering World War II or peacetime veterans under 55 years of age receiving compensation for service-connected disabilities, was started in 1954 and will be completed in three to four years. . . . The National Science Foundation estimates that in 1954 the federal government was aiding more than one out of every five graduate students and one out of every six undergraduates in all fields of science. This and other information is in a foundation study, Federal Support for Science Students in Higher Education. . . . The first organizational meeting of the Defense Science Advisory Council was held in late September at the Pentagon. Invited to the first meeting, which was devoted to planning future activities, were 18 leading scientists and engineers representing various technical fields and organizations.

Results With

'ANTEPAR'®*

against **PINWORMS**

In clinical trials, over 80% of cases have been cleared of the infection by one course of treatment with 'Antepar.'

***SYRUP OF 'ANTEPAR'** Citrate brand Piperazine Citrate

Bottles of 4 fluid ounces, 1 pint and 1 gallon.

***TABLETS OF 'ANTEPAR'** Citrate brand Piperazine Citrate

250 mg. or 500 mg., Scored

Bottles of 100.

Pads of directions sheets for patients available on request.

BURROUGHS WELLCOME & CO. (U.S.A.) INC.
Tuckahoe, New York

Upjohn
KALAMAZOO

Indicated
in most conditions
in which oral cortisone
or hydrocortisone is effective
Available in 1 mg. and 2.5 mg.
tablets in bottles of 100, and in 5 mg.
tablets in bottles of 30, 100, and 500
Usual dosage is ½ to 1 tablet three or four
times daily

Delta-Cortef*

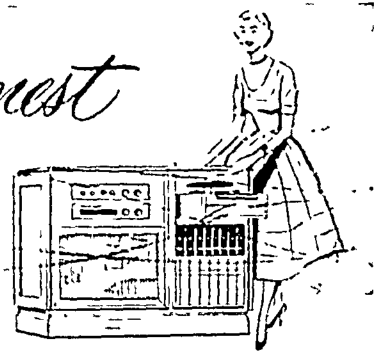
Less sodium retention, less potassium depletion

*Trademark for the Upjohn brand of prednisolone (delta-l-hydrocortisone)

"BUILD-IT-YOURSELF" AND ENJOY

high fidelity at its finest

IN KIT FORM



Heathkits

Anyone can build high quality Heathkits from the complete instructions supplied. Experience the thrill of "building it yourself," and then sit back and enjoy virtually distortionless musical reproduction in your living room. Heathkits provide symphony-hall tone quality for the really critical listener, and are the finest electronic kits available at any price.

❶ Heathkit High Fidelity FM TUNER KIT . . .

A high-gain, stable FM tuner incorporating its own power supply. Matches the WA-P2 preamplifier in appearance. New-design circuit features latest miniature tube types.

MODEL FM 3
(with cabinet)
Shpg Wt 7 Lbs
$24.50

❷ Heathkit 25 WATT HIGH FIDELITY AMPLIFIER KIT . . .

Williamson-type amplifier kit features special Peerless output transformer and KT-66 tubes. Incorporates the very latest design features for exceptional performance.

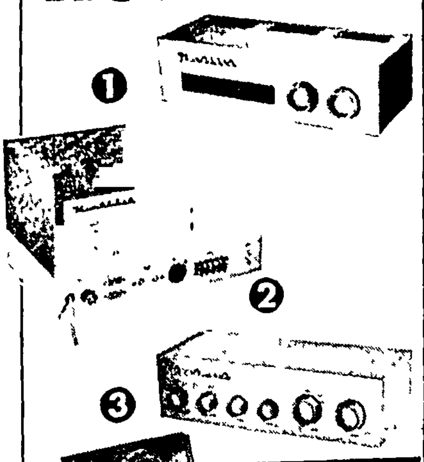
W-5M Main Amplifier with power supply
Shpg. Wt. 31 lbs., Express only . $59.75

W-5 consists of W-5M kit above and WA-P2 kit listed below. Shpg. Wt. 38 lbs., Express only . . . $79.50

❸ Heathkit High Fidelity PREAMPLIFIER KIT

Designed for remote control, compensation and preamplification with Heathkit Williamson Type Amplifiers. Meets most rigorous hi fi specifications. Beautiful satin-gold finish.

MODEL WA-P2
Shpg Wt 7 Lbs
$19.75



Free CATALOG
Describes more than 65 top-quality electronic kits. Write for your free copy today!

ALLERGY—AS IT IS AND AS IT MIGHT BE

Samuel M. Feinberg, M.D.
and
Alan R. Feinberg, M.D., Chicago

• *The diagnosis and treatment of allergies have been greatly facilitated by the discoveries of the past 50 years, but much of the available knowledge of the subject is not being applied. The greatest obstacle to such application is the inadequate background of allergy imparted to the students as part of their general training in medical schools; in addition there is a shortage of fully trained specialists. The effective use of diagnostic tests, of preventive measures, of specific treatment, and of such nonspecific treatments as the sympathomimetic and antihistaminic drugs depends on further progress in education and research.*

Seventeen million people in this country have allergies. This is an estimate of the number of people in the United States who suffer from one or more manifestations such as hay fever, asthma, perennial rhinitis, eczema, contact dermatitis, urticaria, allergic headache, serious drug reactions, and other allergic conditions. Many of these allergies are serious and occasion considerable economic loss and sometimes permanent disability. For example, the pulmonary cripple from asthma is many times more common than the poliomyelitis cripple. In addition, the role of allergy in infectious diseases makes it apparent that everyone may have a personal interest in this field. It is our purpose here to examine what we know about allergy, what we are doing about it, and what we might do to improve the lot of these sufferers.

Even before von Pirquet coined the term "allergie" 50 years ago, the nature of hypersensitiveness was not altogether unknown. The relationship of pollen had been definitely established about 35 years before that; specific causes of asthma had been recognized; the hereditary nature of asthma, hay fever, and related disorders had been established; and the principles of anaphylaxis were being laid down. In the 50 years since von Pirquet's historic pronouncement, allergy has become increasingly known to the profession and public and much has been learned about it. It may be added that, in spite of the fact that the early pioneering work had been of European origin—such as the discovery of pollen as the cause of hay fever by Charles Harrison Blackley of Manchester, England; the concept of allergy by Clemens von Pirquet of Vienna; the principle of specific desensitization by John Freeman of London; and the presence of an allergic antibody by Prausnitz and Küstner of Vienna —the subsequent clinical and experimental development of the field of allergy has been mainly an American accomplishment. In its scientific activity, clinical application, and general interest and information, the United States leads the world in this field.

Much is known about basic mechanisms in allergy. Many phases of the nature of antigens and antibodies are understood, and many others are under study. We are learning more and more about the chemical and immunologic characteristics of the reaginic or sensitizing antibody and the blocking or protective antibody, particularly with newer modifications of electrophoretic and other physical techniques. The role of histamine released by the antigen-antibody reaction is quite well known. Increasing knowledge is being accumulated on the allergic mechanism in the production of hemolytic anemias, other blood disturbances, and autoantigen-antibody processes. In the study of infections and collagen diseases the role of allergy has found increasing interest.

Recognition of specific causes of allergic diseases is on the increase. In the majority of cases of seasonal allergy we can determine a specific cause. First pollen was recognized as a common cause, while 20 or more years ago molds began to be accepted as an important group of allergic causes. Now insect dust is being considered as a possible important additional category of specific etiology. The role of dandruffs of animals in the causation of nonseasonal respiratory allergy is well known. House dust as a common cause of nasal and bronchial allergy is an accepted fact, even though

we do not yet understand the origin of the antigen in it. Thus we can attribute specific allergic causes to about 60% of the cases of chronic asthma and perennial rhinitis. We appreciate also the role of specific foods as causes of allergic manifestations such as eczema, urticaria, headache, and respiratory syndromes. A host of substances causing contact dermatoses has been uncovered both in industry and in the home. The importance of allergy to drugs is being increasingly appreciated, and studies are going on to determine their mechanism. The possibility of bacteria and viruses acting as allergens is receiving increasing attention.

Diagnosis in allergy has as its objective the recognition of the syndrome as allergic, the recognition of complications, the uncovering of unrelated disease, and the establishment of a specific cause for the allergy. It is quite obvious that such a survey depends on a consideration and understanding of procedures in medical appraisal as well as a use of specialized immunologic principles and techniques. Skin tests are important, but their proper use and interpretation and the consideration of the patient as a whole are even more important. At any rate, good practice in this field can result in correct diagnoses and appraisal in a large percentage of respiratory cases and in a lesser number of other types of allergy. Incomplete or misguided ideas about the role of skin tests can increase the misdiagnoses to a considerable extent.

Specific treatment in allergy has made considerable progress in the last several decades. We know how to eliminate allergic causes in foods and inhalants. We have found nonallergenic substitutes for allergenic cosmetics, pillows, mattresses, and drugs. We have learned how to minimize exposure to air-borne allerens by plastic casings, filters, and precipitators. We ave surveyed various parts of the country for their ollen and mold content and know where certain patients may obtain relief and others not. Desensitization to inhalant allergens has become a procedure increasingly accepted and has resulted in relief to ndreds of thousands of sufferers.

Nonspecific treatment has made progress also. To the sympathomimetic drugs have been added the antihistamines. These have constituted an important addition to our therapeutic armamentarium. It took several years for the general profession and public to realize that the antihistamines are not a panacea for allergy. The adrenocorticosteroids and corticotropin (ACTH) gave us additional weapons in the fight against severe allergic diseases. The tranquilizing drugs also promise to be of some help.

Inadequate Application of Progress in Knowledge of Allergy

In spite of these advances in our knowledge of allergy, only a small part of the population with allergies is receiving maximal benefits. With 17 million people having allergy and only about 1,000 specialists in the field, it is obvious that the majority must receive their care from general practitioners, internists, rhinologists, dermatologists, pediatricians, and other specialists. Many of these practitioners feel that allergy is either a theoretical or didactic problem and that its application in practice is either unnecessary or undesirable. These are the doctors who allow hay fever to develop into asthma, who watch children develop emphysema while waiting for them "to outgrow" their asthma, who treat skin allergies with topical applications only, and who give penicillin on the slightest provocation, without any thought of the possible severe allergic reactions resulting. There are those who would rather ascribe their patient's asthma to emotional influence than to go through the laborious search for an allergic cause. These are the doctors who would banish their asthmatics to isolated areas in the quest for climatic cures, instead of realizing that in many instances the "climate" may be the dog, the feather pillow, or the occupational dust.

Many other physicians have gone to the other extreme. According to their interpretation what is not known is allergic. Thus they may regard psoriasis, acne, and nervousness as allergic manifestations. They may put total faith in skin tests and may eliminate every food that gives a slight reaction, true or false, on intradermal testing. They may go to extremes in diet, eliminating refined foods and making life unnecessarily miserable for the allergy sufferers. They are frequently led to give desensitizing injections with avoidable inhalant allergens, with insect pollinated pollen, and even with foods. In short, they believe and practice a kind of allergy of the extremist. The net effect, of course, is that these practices finally result in disrespect of other practitioners and the public for the field of allergy.

Whether he leans to one direction or the other, in the majority of cases it is not the fault of the practitioner. The chance is overwhelming that as a resident in internal medicine or any other specialty he had no exposure whatever to an allergy service or guidance from one trained in allergy. If he had an opportunity to obtain such exposure he ignored it, because in his internship he also failed to get even a smattering of allergy experience and thus his interest was not aroused. This lack of facilities or interest in his intern year was in large part due to the fact that in his medical school he had had little or, in some instances, no contact with instruction in allergy. Of 70 medical schools that replied to a recent questionnaire, many gave only four or five hours of teaching in allergy, while 26 gave none.

There is also a shortage of fully trained allergy specialists who have had adequate training in internal medicine or pediatrics and who have received at least one year of special training in allergy. At this time there are only 34 approved residencies in 18 institutions, and many of the openings remain unfilled. Obviously an insufficient number of young well-trained internists or pediatricians are interested in specialization in allergy. Some of the reasons they give are that (1) allergy is to narrow a field; (2) its clinical application and results are inadequate; (3) it does not offer a challenge; and (4) it is not treated with proper respect and seriousness in medical schools, hospitals, medical organizations, and in the eyes of many physicians. In all respects the young men are in error, except perhaps in regard to reason 4. As to the other reasons, the thinking is based on inadequate contact with allergy during undergraduate training. As to respect of the profession for this specialty, this would be entirely adjusted if a larger number of well-trained young men would enter the field of allergy and would themselves engage in teaching, practice, and research.

But what of the practitioner who recognizes that his teaching in allergy has been inadequate? What can he do? Short, intensive courses are available in connection with the two national allergy societies, the American Academy of Allergy and the American College of Allergists, and also by the American College of Physicians. Other courses of varying duration are offered by different institutions from time to time. The meetings of the national and regional or local societies usually afford considerable stimulus to one who has been already somewhat indoctrinated.

More teaching at the undergraduate and graduate level must be done if we are to overcome the lag between available knowledge of allergy and its actual proper application in practice to the hordes of allergy sufferers. The public also needs to be educated by personal contact, lectures, magazine and newspaper articles, popular books, radio, and any other proper channels. And this job should not be left to the punsters, the sensational lay science writers, and others who know little about the subject but are willing to tell a lot. This is a job for the well-informed physician, and, if done properly and ethically, without thought of personal gain, no one should object.

Inadequacies in Our Knowledge of Allergy

If our present-day knowledge of allergy were widely applied the care of allergic patients would be tremendously improved, but we would not feel satisfied altogether with its status quo. Only by admitting imperfections in our knowledge can we lay the foundation for overcoming them. We do not know all causes of allergy. In the perennial rhinitis and asthma group we can find an allergic cause for 50 to 70%. But what about the other 30 to 50%, in many of which cases patients also have eosinophils in the sputum or nasal smear? In many cases of atopic dermatitis and in more of the urticarial dermatoses we cannot find an allergic cause. Are they allergic or do they have some other background? Why does a patient fail to react to foods and yet be clinically allergic to them? What is the explanation of the lack of skin reactivity to drugs? An understanding of this might explain some of the puzzles of unidentified allergy. There is some basis for believing that a better knowledge of bacterial and viral allergy might help to unravel some of our present mysteries. The concept of sensitization to one's own modified tissue substances needs elaboration.

Desensitization is an accepted principle, but it needs to be improved. Many physicians and patients balk at its long-term programs, its frequently incomplete results, and the inconsistent duration of its effects. Much work is needed to make such treatment simple, safe, and lasting. This may be accomplished finally by such procedures as slowly absorbing antigens or modified antigens or by separation of haptenic from complete antigens. Such and similar goals presuppose a better understanding of the nature and chemistry of antigens and their antibodies and the products of their interaction, the persistence of antigens in the body, and the inherent differences between different types of antibodies.

It would help us to know many other basic facts. How do weather factors operate to influence allergy? To what extent can emotional and other psychic factors affect such conditions as asthma and urticaria? And what is the mechanism involved? What takes place immunologically or biochemically when a person with chronic asthma becomes temporarily relieved during an acute extrarespiratory infection? And might not an isolation of such a chemical mediator be applied to therapeutic use? Granting hereditary influence, what makes some people acquire allergy at one time and others years later, when all are exposed to the same environment?

These and many other puzzles require solution to help perfect our knowledge and practice of allergy. Many of such problems are being investigated in a growing number of institutions. The difficulties encountered are twofold: finances and personnel. Financial support of research appears to be shortening the gap quicker than the personnel problem. The newly organized Institute of Allergy and Infectious Diseases of the National Institutes of Health should aid materially in this support. The American Foundation for Allergic Diseases, organized by the two national societies, is progressing in its goals. It is beginning to foster fellowships and student scholarships and educating the public. Perhaps the bigger problem is manpower. Serious research in allergy requires biochemists, immunologists, physiologists, pharmacologists, physicists, and others. It must be done by teamwork with those who have clinical experience, interest, and understanding of the research needs. There are not enough basic scientists interested in this field, but their interest is growing and such teamwork is increasing. Accomplishment will breed respect; respect will result in interest; and interest will influence devotion of scientists and young clinicians to the field, which in turn will result in good research. Thus the cycle will be completed and continue to enlarge.

Summary

Allergic manifestations are many, affect millions of people, and result in extensive economic loss and disability. In the last 50 years much progress has been made in our knowledge of allergy, which makes it possible to diagnose and treat satisfactorily a large percentage of sufferers. Perhaps the greatest obstacle to maximum benefits of the care of these millions is the inadequate background in allergy possessed by many practitioners because of the meager teaching of allergy in medical schools. Imperfections in our knowledge of allergy and its more adequate management will be remedied by the increasing trend in research and the recent participation of national organizations that aim to support it.

185 N. Wabash Ave. (1) (Dr. S. N. Feinberg).

RADIATION—HELPFUL OR HARMFUL?

Mitchell R. Zavon, M.D., Cincinnati

• *The misuse of ionizing radiations for the treatment of benign conditions is still being recommended and practiced. Textbooks continue to list indications for hazardous uses of radiation without giving critical evidence of benefit. There is evidence that neither the new nor the established practitioners are being reached by recent information about the proper use of radiation and the need of protection. Fluoroscopy in particular is often done under conditions recognized as unsafe. For the safety of the patient, the physician, the nurse or technician, and others who may be helping, the physician who uses x-rays or radium should make sure that the newer knowledge of radiology is being applied in his practice.*

In an adaptive society such as ours, we change with the times or fall behind in the race. Of all the groups in our society, the medical profession has probably had to adapt to changes in as rapid a fashion as any other group. This has been particularly true in the last 50 years. This period has seen the introduction of undreamed of diagnostic and therapeutic tools. As in all groups, some have been able to keep pace with changes and some have fallen by the wayside. All in all, the profession has made a valiant effort, and a largely successful one, to keep medical practice abreast of scientific developments. Perhaps this is an opportune time, however, to ask that some of this "progress" be reevaluated and each of us inquire of ourselves what we are doing and where we are going. We might also inquire collectively whether we are bringing the fruits of progress to each other in our respective specialties, inasmuch as the human body is no respecter of the artificial bounds delineated by the specialty boards.

There are many trite phrases that are useful, if only to remind us in which direction to look. "Familiarity breeds contempt" is one such phrase. We were all startled by the news of the consequences of the atomic bomb, but x-rays and radium, the same horse in another color, have been used in medicine and by physicians for half a century. Why is it that the physician remains in awe of the atomic bomb and radioactive fall-out, but thinks nothing of the hazards of his x-ray equipment or the radium in his desk drawer? I ask this question only rhetorically, for the answer has been given: "Familiarity breeds contempt."

So common has the use of radiation become that it is not unusual to learn of the patient who goes to the physician who has a fluoroscope in preference to the man who does not include the use of that device in his physical examination. The public has come to expect the use of the x-ray and even to demand such use. What I should like to discuss is the medical use of ionizing radiation, the position of the medical profession in the use of this medium, and the implications of such use in the practice of preventive medicine and public health.

Primer in Radiation Physics

In order to make the terms understandable, let us briefly list a few types of radiation, their symbols, and their generally accepted relative biological effect. With the effect of x-rays used as 1, the relative biological effect of alpha (α) rays is 10-20; of beta (β) rays, 1-5; of gamma (γ) rays, 1; and of neutrons (n), 1-10.

All these types of radiation are called ionizing radiations, that is, their passage through matter produces charged particles either directly or indirectly. Ionization, and possibly other effects, can cause damage to living cells, and it is for this reason that we as physicians are usually interested in ionizing radiation.

Primer in Radiation Biology

The biological effects of any of these radiations are dependent on: (1) the type of radiation and its ionization density, (2) the tissue irradiated, (3) the amount of tissue irradiated, (4) the duration of irradiation and dose per unit time, and (5) the organism irradiated. Simply stated, radiation might be described as accelerating the aging process. It can cause a shortening of the life span. It can also cause many of the degenerative changes associated with the aging processes such as carcinoma, sarcoma, and cataract formation. We have all, I am sure, seen some of the bad results of working under the fluoroscope. In the older practitioner we may see signs of radiation exposure such as dry, cracked fingernails, increased keratinization on the hands, and cutaneous malignancy. Such changes may also be signs of advancing age. The increased incidence of leukemia among physicians as opposed to the general population has been written about on many occasions [1] and attributed to radiation exposure. Though the numbers involved are small, the statistical evidence appears to be valid.

Sterility resulting from radiation is largely a folk tale. It requires more radiation to cause sterility than it does to cause death, unless the dose be localized to the reproductive organs. Thus, death will usually occur before sterility. Unhappily, this information does not appear to be known to the average medical practitioner, and the feeling often prevails that, because the power of procreation has not been impaired by 10 or 15 years of radiation exposure, no significant effects have resulted. It is not my objective to discuss the biological effects of radiation in detail. That subject has been treated at great length by those better qualified than I.[2] I do propose to discuss the use to which radiation is being put by the physician and the training he is given for his use of radiation.

From the Kettering Laboratory, Department of Preventive Medicine and Industrial Health, College of Medicine, *University of Cincinnati.*

Read before the Section on Preventive and Industrial Medicine and Public Health at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

Use of Radiation by the Physician

With the exception of the use of radioisotopes for diagnostic and therapeutic purposes and the therapeutic use of radium and its daughters, the physician generally confines his use of radiation to the x-ray. The other types of radiation I have mentioned, alpha, beta, and gamma, are literally Greek to the average physician, and the neutron is used therapeutically in only a few places in this country. The x-ray is, however, used widely throughout the profession, both diagnostically and therapeutically. If one picks up a specialty textbook chosen at random and lists the uses of radiation in the specialty, a rather interesting collection of disease entities results.

For example, Curtis and Huffman[3] describe the use of radium implantation in uterine hemorrhage and in checking menstruation in healthy young women. Ormsby and Montgomery[4] list roentgen ray treatment as being of value in "keloid, tuberculosis verrucosa cutis (at times in lupus vulgaris), and forms of eczema, lichen planus, psoriasis, tinea capitis, favus, furunculosis, carbunculosis, erysipelas, granuloma pyogenicum, hidradenitis suppurativa, and other pyogenic infections, verrucae of different types, and in selected cases of pruritus vulvae et ani." Other disease entities are included as well, such as eczema and psoriasis, for which soft x-rays (grenz rays) are recommended. Casgrande and Frost[5] suggest that "x-ray therapy may be used alone or in conjunction with suprascapular nerve blocks using novocaine," for bursitis of the shoulder.

Many currently used textbooks list other nonmalignant entities for which radiation therapy is suggested. Current professional literature indicates that radiation therapy is being used fairly generally for nonmalignant disease. The increased awareness of the biological effects of radiation makes it more necessary to inquire about the effect of radiation on man. Do we have information as to the relative value of radiation versus other modalities in the treatment of nonmalignant conditions? In the treatment of malignant disease, there can be no question of even considering the delayed effects of radiation. In the treatment of nonmalignant disease, this same principle does not usually hold true, and we must then consider the voluminous clinical evidence of long-delayed effects from such treatment.[6]

Statistically valid, controlled studies, contrasting radiation therapy with other types of treatment of nonmalignant conditions or with no treatment, are either lacking or not generally known. In how many instances of radiation treatment of nonmalignant conditions is the situation after radiation therapy better than the situation before therapy? In how many instances is the delayed effect—10, 15, or even 30 years later—malignancy? Only rarely are such cases reported, and rarer still will be the case of the patient returning when the treatment is unsatisfactory to the physician who initiated treatment. I do not believe that anyone at this time knows the answers to these questions, but we do need the answers.

Recently investigations have been reported that give partial answers to some of my questions. To cite but two, I might mention the studies by Aub and others[7] and those of Simpson and co-workers.[6b] On the other hand, we have the work of Muller on genetic effects of radiation and the attempt to refute them by citation of a follow-up for several generations. When, according to Muller,[8] genetic effects may not show up for 20 or even 40 generations, it is a little absurd to attempt to refute such a statement with a follow-up of only three generations. The few suggestions that the medical profession be aware of genetic hazard from radiation and attempt to minimize such hazard have often been met by a type of polite ridicule. It is unfortunate that our medical training has not prepared us to receive this awe-inspiring possibility with an open mind. To minimize the possibility of damage in utero, the suggestion has been made that the chest film of the pregnant woman be taken with a leaded apron draped from her waist. This suggestion has generally been met with a smile or with open hostility. Thus, by not recognizing the possibility of danger, there is no danger. This is a dangerous doctrine.

Training of the Physician

It is a rare internship or residency, other than that in radiology, that includes experience in the radiology department or gives formal training in how to perform the radiological procedures that the future practitioner may be called upon to perform. How many internists have been shown, in the course of their training, how to use a fluoroscope in order to get the most out of the instrument with a minimum of danger to either the patient or themselves? How many orthopedic surgeons are taking films in the operating room during a hip-pinning without someone to hold the cassettes? How many residents in dermatology receive adequate training in the use of radiation therapy as commonly used in their specialty? By adequate training, I mean the type of training that the radiation therapist will accept as of good caliber Chamberlain[9] has written about the training of the nonradiologist: "Other physicians who need to use radiation in certain fields, can, and should, receive training in the special problems of radiation protection. To omit this important training for even the use of chest fluoroscopes or occasional radiography is the equivalent of omitting the basic training in any of the medical fields in preparation for the use of life-giving but potentially dangerous agents . . . ." Unfortunately, most of Dr. Chamberlain's fellow radiologists do not appear to share his feeling in this regard. Yet interns and residents complete their training and go into the world to practice medicine. For convenience or other reasons they purchase x-ray equipment and use it whether or not they happen to have had adequate training.

In a recent survey of one area, widespread use of the fluoroscope by pediatricians was noted.[10] Of some 35 fluoroscopes studied, less than one-half dozen could come close to meeting current standards.[11] There were numerous examples of equipment that generated more than 20 r per minute at the table top as contrasted to the present recommendation of a maximum of 10 r. Almost without exception, the pediatricians in office practice failed to carry out dark adaptation fully, many taking no time at all. To compensate, the screen brightness was increased, thereby increasing dosage to both patient and physician. Many of the physicians surveyed used neither protective gloves nor aprons. Many x-ray machines had inadequate filtration, inadequate cones, faulty shutters, and unprotected high-voltage wires. Ungrounded equipment was common, to mention an easily remedial nonradiation hazard. Though five of the physicians seen showed some evidence of radiation damage, it was the low-usage factor that undoubtedly prevented more extensive damage to the physician. Some of those surveyed do routine fluoroscopy of each child. I know of no figures indicating the value of this procedure to balance against the possibility of unnecessary radiation exposure.

What is most disquieting is that the situation described in 1955 is virtually unchanged from that described by Buschke and Parker in 1942 in Seattle.[12] They found failure in equipment not different from that our study again showed in 1955. The studies by Sonnenblick in New Jersey highlight the difference in usage between the radiologist and the nonradiologist.[13] He found that, for similar-sized patients under a fluoroscope, a radiologist might be using 1 ma. and producing a dose rate of 2 r per minute at the panel, the internist 2 ma. with a dose rate of 20.3 r per minute, and the pediatrician 5 ma. with a dose rate of 43.8 r per minute. Although these are not necessarily representative figures, the acceptable level at the time of this survey was 20 r per minute. The acceptable output is now 10 r. In my experience, office use of fluoroscopes seldom approaches these standards.

There is no evidence at this time that the information about protection from radiation and proper usage is reaching either the new or the established practitioner. Evidently the newer knowledge and the increased importance being attached to unnecessary exposure to radiation are not being disseminated to our aining institutions. The physician is not alone exposed to radiation. In addition to the patient, there are often the nurse, the technician, the nurse's aid, the student nurse, and anyone else who may be helping out. These people are additional responsibilities and additional reasons why the physician's training in the use of radiation requires improvement.

Needs of the Future

The uses of radiation in medicine and industry are widening yearly. Such an increase in usage correspondingly increases the likelihood of radiation exposure in a larger percentage of our population. To this increased use must be added the extra increment, however small, of radiation from atomic and hydrogen bomb fall-out. Because of our knowledge of the biological effects of radiation, it becomes increasingly urgent, as one of our responsibilities for the public health that we answer certain questions regarding medical usage of radiation and the training of the physician for that usage. The following are such questions. 1. What results from radiation therapy of nonmalignant conditions would be as well or better accomplished by other modalities of treatment? 2. What radiodiagnostic procedures are of value in specified situations and how often is it worthwhile to repeat the same procedure? 3. Is there really any value in limiting radiodiagnostic procedures in females in the reproductive age to the period immediately after menstruation as has been suggested?[14] 4. Can adequate training in specific diagnostic or therapeutic radiation techniques be given all medical practitioners as well as the specialist in order to satisfy minimum professional needs? 5. Will the radiologist assume responsibility for the training of other physicians in radiation in order to satisfy their minimum requirements in the use of radiation?

A last question might well be whether the physician, the physicist, or the engineer is to assume responsibility for the health of the population in relation to actual or potential exposure to radiation. The medical profession must be willing to concern itself with more than just the care of the patient; it must assume its full place in the public health picture with concern for the prevention of disease as well as its treatment. The concern for protection from radiation damage is a legitimate medical responsibility that will be assumed by others less able by training to evaluate the potential biological hazard, if the medical profession as a whole does not assume the responsibility.

Comment

In summation, I should like to quote from the preface to a recently printed booklet on protection from x-rays.[11] This booklet was issued by the National Committee on Radiation Protection, a group consisting of representatives of most of the professional and official groups concerned with radiation.

> The increasing use of ionizing radiations makes it necessary for the medical profession to exercise great caution and restraint in the use of these agents. Current methods and practices should be reviewed to see if the same result could be obtained with less radiation . . . Dermatologists and radiologists should avoid as much as possible the use of radiation for the treatment of benign conditions of persons occupationally exposed to radiation. It should be the duty of the physician, when prescribing radiation treatment, to ascertain if the patient is occupationally exposed to radiation.

I would add only that, if the x-ray equipment and the radium in the hospital or physician's office were treated with as much respect as the nuclear reactor and if safety requirements were as stringent as they were with intravenous therapy in the early days of intravenous therapy, we would have no question of difficulty. Unless some action is taken to improve conditions, we shall see a steady growth of regulating legislation such as has already been promulgated in one or more states. With such regulation must inevitably come restrictions on individual freedom in medical practice.

CLINICAL INVESTIGATION IN NAVAL HOSPITALS

Howard T. Karsner, M.D., Washington, D. C.

• *The pursuit of clinical research in naval hospitals is advantageous to the hospitals themselves, to the Navy, and to medical science in general. Such clinical research is at present based on a well-defined program only to a limited extent; to some extent it depends on the initiative and special interests of individual medical officers. Research projects, whether individual or organized, are encouraged in every way consistent with regulations. Continuity of research can be favored by establishing clinical investigation centers, by association with universities, and by various other means. The financing depends ultimately on appropriations from Congress for the over-all research of the Department of the Navy. The public needs to be impressed with the fact that in the naval hospital every advantage is taken of facilities to improve the care of the patients.*

Just as is true of the civilian hospital, the main purpose of the naval hospital is the care of the patient. The doctors, administrative personnel, nurses, dietitians, and secretaries have much the same function in both types of hospital. This is true also of acquaintance with the literature, attendance at scientific meetings, conferences with personnel of other institutions, staff meetings, seminars, and teaching of house officers, nurses, and other students. With these similarities, there are also differences in staffing, administration, and other functions in the two types of institutions. There is, however, a unity among naval hospitals, in that the pattern of operation is the same throughout, so that service in one hospital is directly continued with transfer of personnel to other hospitals. In many civilian hospitals, research is active and extensive, but this has been only moderately developed in the group of naval hospitals. The purpose of this paper is to indicate how clinical research in naval hospitals is currently conducted and how it may be expanded.

Naval Medical Research

Medical research in the Navy is conducted (1) in research laboratories of the medical department, (2) in naval hospitals, and (3) by contracts with extramural agencies through the biosciences division in the Office of Naval Research. Inservice research is under the direction of the surgeon general of the Navy, but this function is administered by the research division of the Bureau of Medicine and Surgery, with the aid of the medical research advisor to the surgeon general. The laboratories cover a broad spectrum of medical research, from fundamental studies to operational problems such as those of naval aviation and submarine medicine. Details are covered in other publications. Projects submitted to the Office of Naval Research are referred to the research division of the bureau for comment and funding. By this means universities and nonprofit research agencies undertake studies that fill in gaps in knowledge and otherwise aid the broad field of medical research of the Navy. With the cooperation of the bureau, of the Office of Naval Research, and of civilian agencies, an over-all program has been developed, carefully balanced as to the areas of interest and operations. More or less peculiar to the Navy is the fact that projects are initiated by the investigators, who are guided by the over-all program established jointly by the bureau and the laboratories. The higher echelons of the Department of Defense advise in various directions, especially the Assistant Secretary (Research and Development), the Assistant Secretary (Health and Medical), and the Chief of Naval Research. Aid is given by the National Research Council, especially its committee on naval medical research.

In only a limited way is clinical research in naval hospitals currently based on a well-defined program. Doctors in the hospitals, either singly or in groups, undertake projects that are initiated by their interest in a series of cases, in special studies of individual cases, and in methods of diagnosis and testing of therapeutic regimens.

The establishment of clinical investigation centers in naval hospitals must be accomplished within the framework of the hospital and naval regulations. The research projects of individual medical officers, outlined above, are not necessarily based on a program but naturally will be continued. The proposal for clinical investigation centers will provide for programmatic research and is broadly based to include not only the medical officers specifically assigned to the center but also other

Read before the Section on Military Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

officers in the hospital who may wish to participate in the program and carry out such ideas and projects as they may devise in their particular fields. At least three aspects deserve consideration; namely, (1) the advantages to the Navy and to medicine in general, (2) the organizational patterns, and (3) financing.

Advantages of Clinical Investigation Center

The advantages to the Navy and to medicine as a whole are closely interrelated. The advantage to medicine as a whole is obvious, in that new knowledge obtained by research is valuable to all engaged in medicine. For realization of full advantage to the Navy, it is essential that the center shall be an integral part of the hospital. In these circumstances it may well augment the justifiable current pride of the personnel in the medical department of the Navy. The *esprit de corps* is excellent, but the advancement of medical research is calculated to elevate it. With the advantage of productive research, a good residency program, and competent staff members, service in a naval hospital is as attractive as is true of many civilian hospitals. This contributes to procurement of house officers, medical officers, and consultants. It is well known that medical students seek appointments as interns after discussion with their faculty advisors, experienced graduates, and fellow students. The faculty advisors consider all aspects of the hospital program and are guided in part by the research activities to which the intern is exposed. This is also largely true of the experienced graduate and in some measure of the fellow students. However, basic to all this is the reputation of the hospital, and that reputation rests in considerable measure on the teaching provided. There are various factors that make a good teacher, but the main one is inspiration for advancement of knowledge; this inspiration derives largely from productive investigation. In the over-all view, and with only rare exceptions, the best teacher is the man who enlarges his field by research. It does not necessarily follow that only the university hospitals fill the bill, for there are several hospitals without close university connections that are equally desirable from the student point of view.

Procurement is of interest as it applies to the regular medical officers, the reserve officers, and the consultants. It is not to be supposed that all will take part in research, but the stimulus offered by clinical investigation gives support to the hospital duties and may induce some not previously deeply interested to undertake research. Another possibility is that reserve officers on active duty may wish to become members of the regular corps. Important also is the interest of the allied sciences branch of the Medical Service Corps and of other personnel.

Organization

The organizational plan for a clinical investigation center entails consideration of the regular medical officers, reserve officers on active duty, other naval personnel, and civilian employees; sympathy and support by the hospital administration; and association with a university. There are regular medical officers who are dedicated to research and who, despite the policy of rotation, continue their research in different duty stations; however, the policy of rotation is not rigid, and, in special circumstances, an assignment may be prolonged. Reserve officers on active duty have often contributed to the program, but their tours of duty are fixed and their return to inactive status may interrupt projects. Occasionally a reserve officer will extend his tour in order to finish his investigation. The current policy of the medical department of the Navy is to encourage research in every way consistent with regulations, and, in this way, continuity is also preserved.

Continuity is additionally favored by the long service of civilian consultants, but it seems wise to plan for additional assurance. The approach then is via the medium of university association, so arranged that the integrity of the center as a naval establishment is maintained. The closer the university is physically, the better is the outlook.

There are two components, the military and the civilian. It is expected that the staff of the center will be augmented by civilians on a full-time and stable basis. Certainly one or more of these should be clinical men of good background in science and research, who will continue to be motivated by a consuming desire for productive investigation. In addition, there should be civilian scientists qualified in the so-called basic sciences, not necessarily doctors of medicine. These two groups would work harmoniously with the medical officers, consultants, and university authorities. Technical, secretarial, record-keeping, and editorial services are essential.

At this time it seems unwise to plan a definitive table of organization. Much depends on the quality and number of personnel, as well as funds available and other factors. Tentatively it seems practical to think of the operations as being under the supervisory direction of a council or committee composed of two representatives of a cooperating university and two medical officers of the naval hospital.

University Affiliation

The cooperation of a university is highly desirable from several points of view, too obvious to require enumeration. Such cooperation assures the continuing interest of competent investigators in prosecution of the program but at the same time raises a question as to how the civilian component of the center is to be employed. This might be through (1) civil service appointments or (2) contracts. At the present time it seems undesirable to make all employment on a civil service basis, but the reasons would require a consideration of the advantages and disadvantages of this type of appointment beyond the scope of this paper. Therefore, it seems that attainment of the objectives of the center would best be accomplished on the basis of a contract between the university on the one hand and the Office of Naval Research and the Bureau of Medicine and Surgery on the other. The details of such a contract would be settled on the basis of mutual agreement between the agencies concerned. The contract would provide funds for university participation and overhead, the funding to be by the Bureau of Medicine and Surgery. Naturally, any such contract would meet the approval of the command of the hospital. Payment of salaries and wages of civilians employed in the center would be through university channels, except that in some instances there may be a few in the staff who are already civil service employees. These latter are paid directly by the hospital. Those employed on a contractual basis must depend on the good faith of the Navy in the assurance of long-time operation of the center. Since congressional appropriations are on an annual basis, the positive commitments can only be annual; however, there is every indication that the Congress will continue its support in adequate degree. It is to be assumed that the cooperating university may wish to use personnel of the center in such instances as teaching and conducting of seminars. The Navy will welcome such association, and it is likely that the university will confer academic ranks in accord with the attainments in science.

Financing

The financing of medical research in the Navy and its hospitals is somewhat different from that which prevails in civilian hospitals. On the basis of a full acquaintance with the many items, Congress appropriates funds for the over-all research of the Department of the Navy. An allocation is made for medical research. The research division of the Bureau of Medicine and Surgery, with the approval of the surgeon general, further allocates sums for the various phases of medical research. In this allocation are the moneys for research in the naval hospitals and support of the clinical investigation center proposed for the U. S. Naval Hospital, Oakland, Calif.

Comment

There can be no disagreement with the statement of R. H. Williams[1] that the clinical investigator requires (1) clinical wisdom, (2) human relationships, and (3) scientific critique. All these are applicable to naval hospitals, but the human relationships or public relations are especially important in such an establishment as a naval hospital. This justifies a consideration of the social aspects of clinical investigation. The patients in the naval hospital are service personnel and their dependents. The hospital is much in the public eye, even more so than the civilian hospital. The parents and relatives of service personnel must be satisfied that the best of care is given. Studies that are of no direct benefit to patients cannot be condoned. Any experiments that may be dangerous cannot be permitted, and any that may disturb the cordial patient-physician relationship common in naval hospitals are excluded. These social relationships are self-evident. Not so clear is the necessity for impressing on the public the fact that in the naval hospital every advantage is taken of facilities to improve the care of the patients. The naval hospital should take its place among all other medical institutions in providing for progress—progress for the welfare of the whole structure of medicine, both military and civilian.

The opinions expressed are those of the writer and do not necessarily reflect those of the Department of the Navy or the naval service at large.

PSYCHIATRIC INTERVIEW AS TOOL OF MEDICAL DIAGNOSIS

Robert L. Faucett, M.D., Rochester, Minn.

• *Emotional problems or "nerves" are often considered etiological agents of relevance in many conditions for which patients consult physicians. This diagnosis cannot be justified or supported by an evaluation of symptoms alone, but data allowing a positive psychiatric diagnosis should be elicited. The absence of such data should cast doubt on the diagnosis and indicate the need for further investigation. Six case histories illustrate instances in which the use of the above principle was valuable in arriving at a proper diagnosis and planning an effective therapeutic approach.*

Recently much emphasis has been placed on the fact that emotional disturbances account for a great many of the conditions for which patients consult physicians. This emphasis sometimes leads the busy practitioner to accept psychoneurosis as the diagnosis without critical evaluation of the data leading to this conclusion. It is my purpose here to point out some of the pitfalls in psychiatric and medical practice that can arise by the uncritical use of psychiatric diagnosis. The dynamic psychiatric interview, when carefully used, can be an instrument of some precision whose principal ingredients are the skill of the interviewer and his insistence upon being allowed enough time to use his tools adequately. Although the psychiatric interview often may not indicate the nature of the organic disease from which the patient may be suffering, it may cast doubt on psychiatric disease as an explanation and thereby indicate the necessity for further examination.

The psychiatrist who sees patients in diagnostic consultation must be continually aware of this possibility and strive to sharpen his diagnostic acumen and also view his patient as a whole and not only as a psychiatric problem. He must be prepared to exclude psychiatric disease as an explanation of the troubles for which the patients come to him and must be humble enough to request further diagnostic help from his medical colleagues in situations in which he has reasonable doubt as to the positiveness of his diagnoses. The

From the Section of Psychiatry, Mayo Clinic and Mayo Foundation. The Mayo Foundation is a part of the Graduate School of the University of Minnesota

Read before the Section on Nervous and Mental Diseases at the 105th Annual Meeting of the American Medical Association Chicago, June 12, 1956 proper function of the physician is to relieve pain, whatever its cause, and, if the source of discomfort is in the environment, the physician, no less, is required to elucidate the data that make the assumption valid and to discuss his findings with his patient. Failure to assume this responsibility leads the physician to make diagnoses by exclusion. This pitfall is illustrated in case 1.

Report of Cases

CASE 1.—A 37-year-old woman was referred for psychiatric evaluation primarily because of the incompatibility of her many complaints with any recognizable pattern of organic disease. Her chief complaint was of sudden sensations in any or all parts of her body that appeared when she was upset or irritable, when she heard sudden and unexpected noises, or when she suddenly moved her neck, although these sensations could not be reproduced during the examination. In addition, she complained of a "bloated abdomen" and a feeling that "something slips in my back" when going up and down steps.

After having a thorough psychiatric history, the psychiatrist noted, "I cannot make a definite psychiatric diagnosis on this patient. Her symptomatology is bizarre, but her general manner and her life history do not impress me as those of a patient who is so emotionally ill as to produce the present somatic picture." After seeing the patient in several more interviews and talking with the husband, the psychiatrist asked for further neurological consultation. She was found to have absent abdominal reflexes, dysesthesia of the soles of the feet, and bilaterally accentuated Babinski reactions. The neurologist felt that the sudden sensations represented Lhermitte's sign, which is pathognomonic of multiple sclerosis, and suggested this diagnosis. When the psychiatrist discussed this diagnosis with the patient, she admitted that a similar diagnosis had been made previously by a competent neurologist elsewhere, but that she had concealed this fact because she wanted an "independent opinion." Further discussion then revealed that she had been responsible for the nursing care of a friend in whom a syndrome of organic disease of the brain had developed and she had been terrified by the thought that she had the same illness as the friend.

An all too common assumption is that people have neurotic symptoms in order to get attention or sympathy or to otherwise influence the behavior of others. The prominence of what appears to be a large secondary gain may often lead to an erroneous psychiatric referral (case 2).

CASE 2.—A 45-year-old married woman came to the Mayo Clinic because of repeated episodes wherein her behavior became peculiar; everything appeared distorted, color vision became faulty, and she behaved as if intoxicated. Upon recovery, she had complete amnesia for the episode. She had been referred to a psychiatrist because in one episode a physician had been called and, while she was awaiting his arrival, she had drunk a cup of cocoa. When he arrived, she was perfectly normal. Shortly after his departure, she again lapsed into "sleep," and her husband called the physician the following morning, which was Saturday. She could be aroused but was confused and disoriented. It was ascertained that the husband had planned a fishing trip that morning and had been prevented from going because of his wife's condition. Further history revealed that many of the previous episodes had occurred under similar circumstances. The psychiatric referral had been made on the assumption that her episodes were calculated to prevent his fishing trips, which she disapproved of. Further investigation revealed a hypoglycemic picture, and her symptoms were reproduced by a 19-hour fast. Operation disclosed a pancreatic adenoma, the excision of which relieved her of the difficulty, a 24-hour fast then being survived with no symptoms. Further history then revealed that, when her husband planned fishing trips, she slept late and did not eat breakfast, and often friends had discovered her in a comatose condition. Both she and they had then reproached the husband for exposing her to such an occurrence.

Neurotic illness does not develop for the reasons described above, but because of the attempt by the patient to achieve some measure of adaptation in the face of intolerable, unconscious emotional conflicts. The secondary gain occurs only after the illness is established. This patient did not give any data to validate a conflict of sufficient magnitude to cause such symptoms, and, once neurosis was eliminated, the procedures leading to a diagnosis were quite simple.

Many years ago Sir William Osler established the valuable dictum that a single diagnosis must be made to explain all the symptoms of the patient. Like all dictums, however, this one loses its value if it is observed too slavishly (case 3).

CASE 3.—A 42-year-old married woman came to the clinic complaining of lethargy, fatigue, insomnia, anorexia, constipation, amenorrhea, and inability to concentrate. She had been referred for electroshock treatment after a psychiatric consultation at home. She described episodes of forgetfulness of recent events in a peculiarly humorous fashion and described herself as "comical." No self-depreciation or feeling of guilt was elicited, however. Medical and laboratory examinations revealed a myxedematous patient with a basal metabolic rate of −39% and a value of 1.0 mcg. per 100 cc. of blood for protein-bound iodine. She was treated with thyroid extract, and the symptoms of myxedema disappeared. Her psychiatric symptoms remained only slightly improved, but since such symptoms are often the last to disappear in myxedema, a period of watchful waiting was decided upon.

The patient was seen eight months later and was adjudged to be euthyroid. The basal metabolic rate was −3%, and the value for protein-bound iodine was 4.6 mcg. She still complained of anorexia, lack of interest in home or family, and crying spells, and, although she was less forgetful, she still had trouble thinking and calculating. The psychiatrist was again impressed by the lack of guilty self-depreciation; as the patient expressed it, "I worry because I do not worry about my situation enough." She expressed anxiety about going down stairs and admitted to have fallen once and had awakened on several occasions with uncontrollable swallowing movements. She insisted that she felt there was something organically wrong with her and that her difficulties were not on a functional basis. Psychological testing revealed a test deficit with occasions of confusion that the psychologist felt to be on an organic basis. An electroencephalogram disclosed a grade 2 dysrhythmia focalizing in the right parieto-occipital region. Pneumoencephalography revealed a communicating porencephalic cyst in this region. No surgical treatment was recommended.

Although nothing could be done to alleviate her symptoms, the patient was glad to have had her own diagnosis confirmed and then to be absolved of "neurotic complaining." Modification of environmental responsibilities left her functioning well at a level within her capabilities.

The psychiatrist in this instance was made suspicious by the absence of some important features of depression in the clinical picture. The patient had many features of depression—psychomotor retardation, fatigue, disturbed sleep pattern, anorexia, constipation, and fits of crying—but missing was a very important criterion for the diagnosis: an endogenous loss of self-esteem and the presence of self-depreciation. In addition, she gave no historical data such as early emotional deprivation that would make her prone to depression, and no data could be elicited relative to shifts in her life situation that would diminish her self-esteem. The possibility that an individual may have two diseases must be constantly borne in mind, especially when one of them is an emotional disease. Perhaps one of the most valuable questions to ask a patient, once a satisfactory rapport has been established, is, "What do you honestly believe is your difficulty?" If the question is asked sincerely, it is surprising how often the patient is able to provide significant leads, as was so in case 3.

Frequently patients couch their complaints in such bizarre language that the physician can only conclude that the individual is psychotic. This is not invariably so, and the physician must be constantly aware that verbal behavior is often an inadequate tool for becoming acquainted with a patient's difficulties (case 4).

CASE 4.—A 61-year-old woman was referred by the ear, nose, and throat department because of her bizarre complaints of "ants crawling in and out of my skull." She insisted that a powdery substance was dropping from her skull to her neck. She was sure that previously a swarm of bees had flown into her ear and had not emerged. She maintained that the insects were really there and that this was not just a mannerism of description. Neurological consultation and x-ray examination of the skull resulted in an opinion that the patient had a tumor in the left frontotemporal region extending toward the base of the skull. Neurosurgical exploration revealed an intradiploic epidermoid cyst that was intruding intracranially; it extended underneath the left frontal lobe and had eroded the base of the skull. The surgeon noted that it was filled with a grumous powdery material "such as might be produced by ants."

The psychiatrist in this case, while being impressed with the bizarreness of the description and the rigid and delusional way in which the patient persisted in this type of description, was not satisfied. He attempted to find other psychotic elements in her behavior such as are frequently present in the patient with a somatic delusion. Patients with somatic delusions can often be led by skilled psychiatric interviewing to admit that they ascribe their difficulties to malignant machinations by persons, specific or nonspecific, in their environment. This patient had no such paranoid ideation nor was she otherwise psychotic, and further investigation revealed the nature of her difficulty.

The physician is often misled by his own emotional prejudice, which has been aroused by the patient's past behavior. This is especially true of those patients who are careless with the truth, ne'er-do-well, or alcoholic, as shown in case 5.

CASE 5.—A 43-year-old man, an unemployed laborer, was referred for psychiatric evaluation because of inability to work more than one or two days a week, fatigue, confusion under stress, backache, headache, and visual disturbance. He gave a long history of inadequate vocational and social adjustment. He had never held a job long and had been alcoholic for many years, being hospitalized for alcoholism three years previously. His life history revealed a long pattern of passive-dependent, immature, and impulsive behavior. He had fallen from a truck five years before, and this was followed by a period of unconsciousness. He had had a careful neurological examination and had been observed in the hospital for several days, but no evidence of intracranial neurological disease was noted. A long series of compensation suits followed this, but these had been settled with finality two years previous to this admission. He had been referred out of desperation by his local physician and the local welfare board because of his inability to remain employed.

Because his behavioristic pattern was relatively unchanged and because the patient described with some detail periods of confusion associated with clear-cut visual disturbances, in that objects to his right were always blurred and that he became confused when more than one object was in the visual field at one time, he was referred for neurological examination. This gave essentially negative results, but x-ray examination of the skull revealed an area of calcification to the right of the sella, which was much more pronounced than was indicated in roentgenograms taken five years previously. A right carotid angiogram did not reveal a mass intracranial lesion. The condition is still being studied, but it has been concluded that he has a right parasellar neurological lesion in addition to his lifelong character neurosis.

In this situation, the patient's severe and lifelong character neurosis, which had led to his poor general life adjustment and passive-dependent traits, made it easy to ascribe his symptomatology to his desire for further compensation, although a careful history revealed the fact that no further compensation was involved and, further, that the patient knew it. He was frank and realistic about his poor adjustment in the past, but there was nothing to indicate that this lifetime type of character neurosis should suddenly revert to a more integrated type of hysterical neurosis, which was the only way his presenting symptoms could be explained.

Comment

The contributions of psychiatry to medicine in recent decades have added a new dimension of rationality to the practice of the art of medicine. The notion of treating the person instead of the disease by use of the rational body of knowledge now accumulated is leading to a revolution now known as the practice of comprehensive medicine. This ancient ideal has been more closely approached by new insights into the effects of emotion and life situation on disease processes. But to take full advantage of these insights the knowledge must be used with the criticalness and skepticism that are the hallmark of good medical practice.

The psychiatrist who is asked for a diagnostic consultation on a patient with somatic complaints should endeavor to be as precise as possible in the rationale of his opinion. The positiveness of his opinion can be increased if he finds the clinical picture, psychodynamic history, and psychogenetic history in support of one another. In addition, he should endeavor to explain, from the above data, why the patient felt ill at the particular time he did and why he felt ill with his particular symptoms as an expression of emotional conflict. Insofar as he is unable to satisfy these criteria, the psychiatrist should be quite conservative in his opinion and eager for further investigation.

The practitioner who ascribes the complaints of a patient that could possibly be structurally caused to an emotional cause assumes a grave responsibility. Errors in diagnosis in this direction can threaten the patient's life or at best deny him the benefit of medical treatment, which more energetic diagnostic procedures would make available to him. On the other hand, insistence by the practitioner on a physical cause when the primary problem is an emotional one can prolong the disease and further solidify the patient's objection to psychiatric investigation. Referral of the patient for a diagnostic psychiatric interview may clarify the issue in both instances, provided the psychiatrist effectively brings to bear the tools of his specialty and is humble enough to say occasionally, "I don't know."

ANTIDIURETIC RESPONSE TO PIPEROXAN AS A DIAGNOSTIC TEST OF PHEOCHROMOCYTOMA

Alfred E. Leiser, M.D.
and
Arthur C. Corcoran, M.D., Cleveland

• Observations on the renal functional effects of piperoxan in patients with hypertension due to functioning pheochromocytoma had shown that, in such patients, this drug provokes a decrease in urine flow. This suggested that, with standardized hydration, the effect of piperoxan on urine flow might be useful in the evaluation of patients suspected of these tumors. Accordingly, fasting, recumbent patients were given 1 liter of 0.25% solution of sodium chloride orally and urine was collected for three or four successive 30-minute periods, the usual test dose of piperoxan being given intravenously after the second urine collection, when its effect on blood pressure was also observed.

In 3 normotensive patients and 32 patients with hypertension not due to pheochromocytoma, including 7 in whom piperoxan induced decreases of systolic pressure more than 30 mm. Hg, piperoxan had a diuretic effect, in that the volume of the third urine sample exceeded that of the second. The physiology of pheochromocytoma was then simulated in seven normal subjects by giving them infusions of levarterenol with and without a mixture of epinephrine. In these the diuretic response to piperoxan was not observed and antidiuresis occurred in those receiving the mixture of the two pressor amines. Further, in two patients with hypertension due to functioning pheochromocytoma, the volume of the third sample (after administration of piperoxan) was substantially less than that of the second urine sample.

The procedure is described as a confirmatory observation in the diagnosis of functioning pheochromocytoma. It seems to have the advantage of giving normal, diuretic responses in patients who show nonspecific depressor responses to piperoxan. Note is also made of the frequent occurrence of "false-positive" depressor responses to phentolamine in patients with essential hypertension under treatment with preparations of Rauwolfia.

Various adrenolytic and sympatholytic compounds have been used in pharmacological tests to establish the presence of functioning pheochromocytoma. None of these tests is conclusive. In the presence of hypertension, the two principal agents used are piperoxan (Benodaine) hydrochloride, which is primarily adrenolytic, and phentolamine (Regitine) methanesulfonate, which is both adrenolytic and sympatholytic. False-positive or depressor responses are observed with both agents, particularly in patients with uremia and also in those taking sedatives and certain antihypertensive drugs.[1] As noted below, false-positive responses are relatively frequent in patients who are taking Rauwolfia drugs and who are tested with phentolamine. Patients with hypertension very often are given barbiturates and/or Rauwolfia drugs and sometimes have uremic conditions, so that the occurrence of false-positive responses confuses the diagnosis of hypertension that is due to pheochromocytoma.

In a study of renal functional responses to piperoxan, Corcoran, Dustan, and Page[2] noted that piperoxan usually was somewhat diuretic in effect in patients who had hypertension from causes other than pheochromocytoma, whereas it was antidiuretic in four patients who had hypertension that was due to pheochromocytoma. The antidiuretic responses were proportionately greater than the falls of blood pressure elicited by the drug. They suggested that, under standardized conditions, the response of urinary flow to intravenous injection of piperoxan might serve as a confirmatory test in the evaluation of the blood pressure response. Accordingly, a simple procedure was devised and tested in patients with normal blood pressure, in patients with hypertension, in two patients with pheochromocytoma, and in persons with normal blood pressure who had been given intravenous infusions of levarterenol or mixtures of levarterenol and epinephrine, thus mimicking the altered physiology of patients having pheochromocytoma. The observations show that the measurements of urine volume constitute a simple, useful confirmatory procedure and, more significantly, that they are an aid in identifying false-positive, depressor responses to piperoxan.

Methods and Materials

The procedure was as follows. Fluid was allowed ad libitum, but food was withheld overnight. At 8 or 9 a. m., 1 liter of 0.25% sodium chloride solution was given orally, usually during the course of 10 minutes, after which time the patient voided. This urine specimen was discarded. The patient was asked not to smoke and to remain recumbent during the test, arising only to void. Urine was collected at 30-minute intervals for three or four periods, and the volume of each sample was measured. Immediately after the second voiding, piperoxan hydrochloride was given intravenously at a rate of 20 mg. in two minutes. While three or four urine collections were usually obtained during this study, the use of the test in diagnosis requires only the collection of specimens immediately preceding and after the administration of piperoxan.

The persons who were studied included 35 as controls. There were 3 with normotensive and 32 with hypertensive conditions. Among those with hyper-

tension, 22 had uncomplicated essential hypertension, 4 had essential hypertension in the malignant phase, 3 had chronic glomerulonephritis, one patient had chronic pyelonephritis, one had bilateral renal artery stenosis,[3] and one had diabetic intercapillary glomerulosclerosis; 7 of the 32 had azotemia (with blood urea levels of 60 mg. per 100 ml. or greater and serum creatinine levels of 2.9 mg. per 100 ml. or more). One patient with functioning pheochromocytoma was studied before and after removal of the tumor. An experimental group of seven healthy volunteers were given infusions of levarterenol or a mixture of levarterenol with epinephrine, during the administration of which the tests were performed as described.

Results

Control Group.—The data for 35 patients are summarized in table 1. Among these patients, 28 (group A) showed little change or an increase in systolic blood pressure; 7 (group B) showed decreases ranging from 30 to 72 mm. Hg and were considered to have false-positive, depressor reactions. Among these seven, four had azotemic conditions. No cause was established for the responses in three patients, although they may have been taking barbiturates. All of these patients (including those with depressor responses) during the 30 minutes after receiving piperoxan showed increased urinary flow as compared with the urinary flow in the 30-minute preinjection period. When expressed as a ratio of urine volume before the administration of piperoxan to the urine volume after it, the values ranged from 0.89 to 0.24, averaging 0.56.

After injections of phentolamine, five of the patients with nonuremic hypertensive conditions (cases 11, 12, 13, 14, and 26) showed decreases in blood pressure greater than 40/30 mm. Hg; the drop in one of these was 62/40 mm. Hg and in another 60/30 mm. Hg. Four of these patients had been taking reserpine, and they lost their depressor responses to phentolamine when the reserpine was withdrawn. None showed depressor responses to piperoxan. The condition of one patient who showed the greatest effect from phentolamine (case 13) was not uremic, nor was he taking a Rauwolfia drug; his responses in blood pressure and urine volume to piperoxan were normal, and a bioassay of the urine indicated no excess of pressor amine.

Pheochromocytoma.—The preoperative and postoperative responses of urine volume in a patient with functioning pheochromocytoma (table 1, case 8) are shown in table 2 (case 36). Preoperatively, piperoxan evoked antidiuresis, while postoperatively it evoked slight diuresis. The early history and findings concerning this young man were summarized by Corcoran, Dustan, and Page.[2] In brief, he was found in 1952 to have bilateral functioning pheochromocytomas. It was not excluded that the tumors were malignant, since they showed mitoses, although there was no evidence of capsular penetration. After operation the patient felt much improved, and his blood pressure returned to normal. However, hypertension slowly and progressively returned, and, about November, 1954, he again noticed excessive sweating and redness of his hands. These symptoms increased, and he was seen again in November, 1955. Whereas the attacks prior to the operation in 1952 had been paroxysmal, no paroxysms were observed during this recurrence.

TABLE 2.—*Preoperative and Postoperative Responses of Blood Pressure and Urine Volume to Piperoxan in Patient with Pheochromocytoma*

	Postoperative, 2 mo.:						
	144/96	—16/14	62	68	88	500	0.8

* Same patient as in case 8, table 1.[2]

On examination, the significant physical findings were persistent tachycardia and a blood pressure of 208/150 mm. Hg. The basal metabolic rate was +49% of normal. The phentolamine test showed a fall of pressure of 62/60 mm. Hg, and the fall after administration of piperoxan was 82/60, the latter being associated with a decrease in urine flow. At operation, a malignant pheochromocytoma was removed from the left renal area, together with the left kidney, to which it was adherent. Postoperatively, responses to phentolamine, piperoxan, and histamine were all normal, including the responses to piperoxan in diuresis, and his condition has remained symptom-free and normotensive for two months.

TABLE 3.—*Blood Pressure and Urinary Flow in Response to Piperoxan in Normal Subjects*

Experimental Group	Case No.	Blood Pressure: Prior to Administration	Blood Pressure: Fall	Blood Pressure: Resting (Preinfusion)	Urine, Vol in Ml: Before Administration 1	Urine, Vol in Ml: Before Administration 2	Urine, Vol in Ml: After Administration 3	Urine, Vol in Ml: After Administration 4	Ratio of Vol of Collections 2 and 3

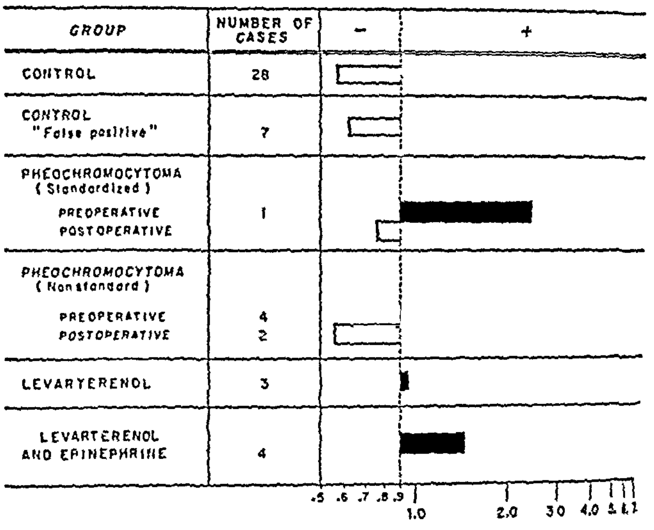
	4	140/68	—26/18	116/68	10	185	95		1.9

Previous observations[2] of the responses in urine volume with administration of piperoxan were not made under the standardized conditions described in the present series. In the former series, four patients with functioning pheochromocytoma had shown antidiuretic responses to piperoxan preoperatively (ratios of urine volumes before and after administration greater than 2), and the two patients tested after removal of the tumors showed diuretic responses with corresponding ratios of urine volumes of less than 1. The observations in the patient in case 36 (table 2), tested under standardized conditions, accord with this experience, in that preoperatively he showed an antidiuretic response to piperoxan that persisted into the second half-hour of urine collection, whereas, after removal of the tumor, the response was diuretic on two occasions.

Experimental Group.—Three healthy male volunteers were infused continuously with levarterenol at rates of 20 to 40 mcg. per minute to maintain the systolic blood pressure in excess of 40 mm. Hg above the resting level prior to performing the studies on response in urine volume to piperoxan. This dosage rate was then maintained throughout the experiment. Four healthy male volunteers were similarly infused with a solution containing epinephrine and levarterenol in concentrations of 1 and 4 mcg. per milliliter, respectively, maintaining an increase in systolic blood pressure that was greater than 25 mm. Hg and a pulse rate more than 30 beats per minute in excess of the resting levels prior to the test. The data are summarized in table 3. Both the depressor and the antidiuretic responses to piperoxan were more striking in the group receiving levarterenol with epinephrine than in the group receiving levarterenol alone. In the latter group the urine volume ratios before and after the administration of piperoxan varied from 0.80 to 1.09, averaging 0.94. In the volunteers infused with levarterenol and epinephrine combined, this ratio ranged from 0.96 to 1.9; three ratios each were greater than 1 and the average ratio of all was 1.2.



Schematic summary of ratios of volume of urine collection taken immediately after administration in control group of 28 patients with hypertension; 7 control patients with hypertension with false-positive blood pressure responses; preoperatively and postoperatively in groups of 1 and 4 patients with pheochromocytoma without uniform hydration, and in 3 normal volunteers receiving infusions of levarterenol and 4 receiving a mixture of levarterenol and epinephrine. The dotted base line indicates the highest ratio found in the control group with hypertension, and the bars are drawn to the mean of the observations in each group

Comment

Pheochromocytoma is a rare cause of hypertension, but its recognition may lead to cure. Any simple procedure that will enhance the diagnostic accuracy of available pharmacological tests is therefore desirable. Infusion of epinephrine or levarterenol in a person who does not have hydropenia has been shown to promote excretion of a dilute urine, the flow greatly diminishing after the infusion has been discontinued.[4] Administration of piperoxan to patients with functioning pheochromocytoma also results in antidiuresis[2] as if by pharmacological "withdrawal" of pressor amine. A like response to piperoxan occurs in healthy volunteers infused with epinephrine and levarterenol and, to a lesser extent, with levarterenol alone. The mechanism of this antidiuretic response is not clearly understood; it is in part attributable to a decreased rate of glomerular filtration.[2]

The antidiuresis that followed injection of piperoxan in patients with functioning pheochromocytoma was marked, the rate of urinary flow decreasing to about one-third for the rate before injection. The urine response after administration of piperoxan appeared to be specific. All controls, whether with normotensive or hypertensive conditions, irrespective of depressor blood pressure response, exhibited increased urinary flow when given piperoxan. Only those with an excess of circulating catechol amines showed antidiuresis.

Among the 32 control patients with hypertension, the greatest ratio of the 30-minute volume of urine before administration of piperoxan to the collection after administration was 0.89; and the average was 0.56. In five patients with proved pheochromocytoma, this ratio was greater than 2 in all instances. After surgical removal of the tumor, the ratio reverted to less than 1 in the case reported above and less than 1 in two other patients having pheochromocytoma who were studied postoperatively by Corcoran, Dustan, and Page.[2] The average ratio in normal experimental subjects in whom only levarterenol was infused was 0.94, whereas infusion of both levarterenol and epinephrine in another group resulted in an average ratio of 1.39. Thus, a ratio greater than 0.9 would suggest a positive antidiuretic response.

We conclude that the procedure described adds to the possibility of diagnosis of pheochromocytoma in office practice. Errors in its interpretation may result from (1) the patient's premature ingestion of the saline load; (2) dehydration or vomiting; (3) pheochromocytoma with paroxysmal hypertension in a normotensive phase; and (4) the presence of a pheochromocytoma that produces levarterenol only.

Summary and Conclusions

Antidiuresis following intravenous administration of piperoxan (Benodaine) hydrochloride was noted in six patients with functioning pheochromocytoma, in four normal subjects infused with levarterenol plus epinephrine, and, to a lesser extent, in three subjects infused with only levarterenol. No antidiuresis occurred after injection of piperoxan into 35 control patients, including 32 with varying degrees of hypertension not due to pheochromocytoma, although 7 of the patients with hypertension exhibited depressor responses that could be classified as false-positive. A simple method, described above, based on the effect of piperoxan on urine volume, may be utilized in an office practice to constitute a useful confirmatory test for pheochromocytoma and, more significantly, as an aid in identifying false-positive depressor responses to piperoxan. False-positive depressor responses to phentolamine (Regitine) methanesulfonate but not to piperoxan were observed in patients with hypertension taking Rauwolfia drugs.

Addendum

Since submission of this paper, the test has been used in the diagnosis of pheochromocytoma in an additional patient (table 4, case 37). The experience demonstrates a further advantage of the procedure, since the widely fluctuant blood pressure levels of this patient vitiated the interpretation of tests dependent solely on measurements of blood pressure. This patient is a woman 58 years old who complained principally of episodes of painless nausea and vomiting, often associated with profuse perspiration and palpitation, which occurred shortly after rising in the morning. In January, 1955, a cholecystectomy was done because of cholelithiasis, with subsequent temporary relief of vomiting, which recurred during the third postoperative month. Diabetes was discovered at the time of operation but was considered mild. She also experienced frequent episodes of nocturnal sweating. The appetite had diminished during the past year, and with this she had lost 20 lb. (9.1 kg.) in weight. She noted polyuria and polydipsia only a few weeks before being seen in May, 1956.

Table 4.—*Preoperative and Postoperative Responses of Blood Pressure and Urine Volume to Piperoxan in Patient with Pheochromocytoma*

	182/104	irregular	25	73	26	28	2.0
	144/90	irregular	38	83	45	...	1.8
	Postoperative, 1 wk.:						
	104/80	none	30	84	480	...	0.17

On examination she seemed tense and anxious, chronically ill, and in a dehydrated condition, with acetone odor to the breath. The initial blood pressure was 230/130 mm. Hg. The urine contained glucose, acetone, and diacetic acid; blood sugar level was 543 mg. per 100 ml.; and plasma carbon dioxide–combining power was 10.8 mM. per liter. She was given fluids and insulin, with relief of these manifestations. However, the diabetic state was severely fluctuant, with wide variations in blood sugar levels and frequent insulin reactions, i. e., a state of "brittle" diabetes. Further, it was noted that the blood pressure was also widely fluctuant, with variations from 230/130 to 70/50 mm. Hg during a single observation period of 10 minutes.

Blood urea level was 27 mg. per 100 ml., and basal metabolic rate +14% of normal. Histamine was given at a time when blood pressure was 116/66 mm. Hg, with an immediate fall to 70/50 and secondary rise to 250/144 mm. Hg, at which point the patient complained of nausea, fulness, and flushing. Phentolamine was given intramuscularly, with an immediate fall in blood pressure to 140/80 mm. Hg. During the subsequent 10 minutes, blood pressure ranged spontaneously from 188/96 to 62/40 mm. Hg.

The piperoxan diuresis test was done on three occasions. The first test was invalidated by vomiting and an insulin reaction. At the second test, blood pressure fell to 82/32 mm. Hg immediately after the injection and shot up immediately to a range of about 200/120 mm. Hg, with subsequent wider fluctuations. The ratio between the volumes of the second and third collections was 2. The third test showed less fall in blood pressure than the second, but the ratio of the volumes of the second and third collections was 1.8. Bioassay of the urine for pressor amine indicated a content equivalent to 280 mcg. per 24 hours, the standard being levarterenol.

A large (about 150 gm.) nonmalignant pheochromocytoma was removed on June 3, 1956. In the immediate postoperative period, the diabetes became much easier to control, there were no insulin reactions, and the patient's blood pressure was persistently low. Three months postoperatively the glucose tolerance test was normal and all evidence of diabetes had disappeared. The experience in this case demonstrates the diagnostic value of the piperoxan diuresis test in a patient with severely fluctuant hypertension. The clinical state of this patient seems to correspond to that of a patient studied by one of us (A.C.C.) and described in detail by Goldner.[5]

2020 E. 93rd St. (6) (Dr. Corcoran).

Drs. E. N. Collins and Penn G. Skillern gave permission to report the case in the addendum.

CENTRALIZED TREATMENT FOR SERIOUSLY ILL SURGICAL PATIENTS

J. Murray Beardsley, M.D., J. Robert Bowen, M.D.
and
Carmine J. Capalbo, M.D., Providence, R. I.

• *The critically ill surgical patient in some instances suffers from inadequate care because of the shortage of nursing personnel. Such patients should be segregated in an area staffed by specially trained personnel; the unit here described has one supervisor, graduate nurses, practical nurses, orderlies, a general duty aide, and a dressing room aide. One full-time surgical resident is assigned to it. The unit is built with certain features, such as glass partitions, that facilitate observation; it is also equipped with certain facilities that never leave this area. Records especially emphasizing the needs of such patients have been developed. Certain administrative problems, such as the selection of patients and their subsequent removal to regular quarters, have been solved satisfactorily. This arrangement guarantees expert care to those who need it most, relieves pressure in other areas, allows a more generous use of auxiliary help, and lightens the demand for private nursing care for the individual patient.*

With the increase in the number and complexity of surgical operations that are being performed, the time has come for a new look at the care of the critically ill surgical patient. This is especially true at this time, since we are faced with a critical shortage of trained graduate nursing personnel. In the zeal for training nurses and doctors and because of the necessity for scientific hospital programs, along with the emphasis on shorter hours of work, there is danger that the patient may become the forgotten man.

The definition of adequate care has ramifications that are far-reaching and embodies a vigilance and a degree of teamwork on the part of well-trained nurses, auxiliary personnel, house staff, and attending physicians heretofore not demanded. The care of the seriously ill surgical patient is a specialized duty and requires nursing skills that can be developed only by continued exposure to this type of problem. The careful attention to fluid balance records, gastrointestinal and thoracotomy tubes, pharyngeal suction, and other equally important facets of the postoperative period are well appreciated by both doctors and nurses.

Patients who have had operations of a less traumatizing type, such as routine herniorrhaphies, appendectomies, vein strippings, hysterectomies, and pilonidal sinus excisions, fare very well, providing they have received the benefits of a period of observation in a recovery room. However, patients who have been subjected to multivisceral procedures for cancer, cardiac or pulmonary surgery, or any difficult major operation imposed on an already physiologically disturbed situation need care that can be provided only on a unit adequately staffed with intelligent, well-trained personnel.

Approach to the Problem

In the past, two methods have been employed in an attempt to solve the problem of inadequate care of the seriously ill patient. The first, a step in the right direc-

---

Surgeon-in-Chief (Dr. Beardsley), Assistant Surgeon (Dr. Bowen), and Surgical Resident (Dr. Capalbo), Rhode Island Hospital.

tion that should continue to be encouraged, has been the utilization of auxiliary personnel as practical nurses and hospital aides. The second is the time-honored use of a private duty nurse for those patients who need constant observation. The latter rules itself out automatically as a solution to the over-all problem, since, with the existing shortage, there are not enough such nurses to go around, even if the average patient could afford them, which he cannot.

The use of auxiliary personnel care is an accepted method of compensating for nursing shortage, but we must all realize that the graduate nurse will always be the key figure. However, on certain shifts it is common practice today to assign only one or two graduate nurses to a busy surgical unit, and much of their time is taken up with administrative duties, which makes it impossible for the critically ill patient to obtain the necessary care. The more efficient approach to the problem is to segregate all seriously ill surgical patients in a single unit that is staffed by personnel especially trained for the job. The care of this type of patient requires specialized training that is on a par with that of personnel assigned to an operating room team. It is, of course, important that their interests be in this realm and that they have the necessary background and motivation.

Another defect in the care of the hospital patient has been lack of cooperation between the various groups responsible for his care. This responsibility rests with the doctor, the nurse, and the administration. The doctor, who is held fully accountable for the patient's progress, has little to say about the planning of the care that his patient is to receive. It is obvious that unilateral planning by any one group not only is a mistake but in addition leads to unnecessary misunderstandings that are easily corrected when there is full cooperation of all concerned.

The philosophy of segregating all seriously ill patients in a single area to be cared for by specially trained personnel and cooperation in the planning of this care have an impact not only in this limited sphere but in the entire hospital and on the over-all problem of nursing shortage. The removal of this type of patient from the general wards sharply reduces the need for graduate nurses in those areas. It also practically eliminates the need for three private duty nurses to be assigned to a single patient.

Physical Facilities

The new Rhode Island Hospital, through the foresight of those concerned with its planning, has incorporated within it two adjacent wings on the same floor that are especially designed for the care of the type of patient under discussion; these are called the special care unit. This area differs from other units in that a nursing station is in the center of each wing in place of the standard nursing station at the base of the two wings. It also has a more liberal use of glass partitions, making it possible for practically all patients to be observed from the nursing stations. In all, there are 28 beds, 16 on one wing and 12 on the other, serving an average surgical census of 295 (127 general surgery patients and the remainder patients in the surgical specialities). The total bed capacity of Rhode Island Hospital is 627. Private rooms are available for those with terminal conditions or for those who would bother others. Sleeping quarters for a full-time resident, a laboratory, a minor surgery room, and a large dressing room are provided. On the same floor, adjacent to the unit, is a conference room equipped with a blackboard and conference table. This unit is on the floor directly above the operating room, which is considered important, since most admissions are from the recovery room, which is within the operating suite. Each bed is provided with a suction outlet, an oxygen device, and sphygmomanometer on the adjacent wall. An emergency switch is conveniently placed near each nursing station, and the signal is heard in the resident's quarters on the same floor.

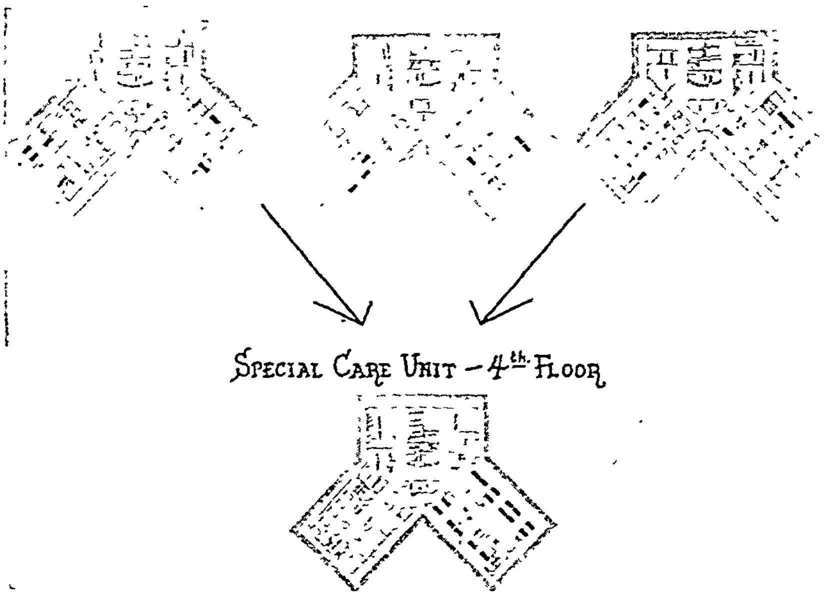

Fig 1.—Graphic portrayal of consolidation of critical surgical patients on a special unit.

Staffing of Unit

At the present time the unit is staffed by one supervisor, two head nurses, nine other graduate nurses, eight practical nurses, four orderlies, one general duty aide, and one dressing room aide. One full-time surgical resident is assigned to this unit. He is usually at the second-year or third-year level and rotates through the unit for a three-month period. He is covered on his nights off by a surgical resident, who is rotating through one of the specialties, usually pathology. In the main, this coverage has been adequate, but it is not ideal. Due to the shortage of personnel, an ideal nursing complement of one nurse for every three or four patients is not available. However, it has worked out reasonably well except on occasions at night when two or more patients with serious problems have been admitted. Since the basic philosophy of the unit is to provide specialized care at all times to patients who are seriously ill, a dictum of nonrotation of personnel has been followed. We consider this to be the most important feature of the program, and it provides a group who are familiar with the patients from day to day. It also has resulted in an almost unparalleled *esprit de corps;* nurses have been known to work two consecutive shifts to cover for an associate unable to report for duty.

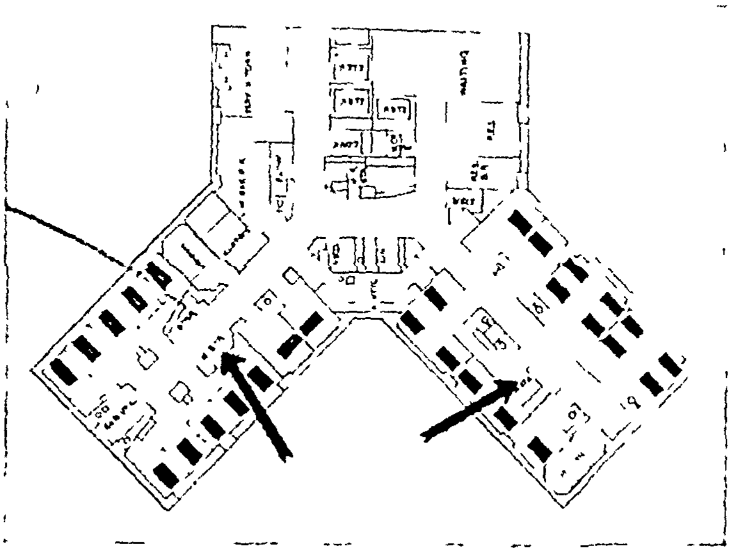

Fig. 2.—Architect's diagram of special care unit. Arrows point to centrally located nursing stations.

Each nurse has been trained to draw blood and administer fluids intravenously. This practical experience is supplemented by instruction on the part of the resident and house staff. In a short space of time, a deeper insight is instilled into all personnel regarding the necessity for accuracy in such frequently neglected items as quantity and character of tube drainage, total daily intake and output, degree of moisture in the tracheobronchial tree, and significant changes in blood pressure and pulse.

Equipment

The interval of time between the onset of symptoms and the initiation of remedial measures in any emergency may be the determining factor in survival. For this reason, specifically listed stationary equipment never leaves the unit. The equipment includes a tracheotomy set, thoracentesis tray, paracentesis tray, adult's and baby's laryngoscopes, adult's and baby's cut-down sets, pneumothorax machine, lumbar puncture set, pneophore, incubator, in-bed scales (Acme), pharyngeal airways, baby's transfusion set, special drug tray, one-bottle and three-bottle chest suction apparatus, an aliquot of crystalloid and colloid solutions for intravenous use, oxygen administration outlets at each bedside, and various types of intestinal decompression tubes.

A standard, well-equipped laboratory is on the same floor, and, in addition to basic items for doing such procedures as complete blood cell counts, hematocrit determinations, and urinalyses, a microcentrifuge is provided, making it possible to do a microhematocrit determination within three or four minutes without doing a venipuncture. This is particularly useful in cases of massive upper intestinal bleeding or burns in which frequent hematocrit determinations are essential.

Records

Certain new forms have been drawn up to allow for consolidation of all pertinent data regarding the patient's status in any 24-hour period. These records are kept on a clipboard at the foot of the bed. On inspecting this clipboard, the first sheet seen is a standard temperature, respiration, pulse, and blood pressure sheet that is used throughout the hospital. The next form is a new fluid balance and burn sheet that is constructed in such a way that the intake and output are summarized every 8 hours and totaled every 24 hours ending at 7 a. m. A space is provided below this total for the recording of the amount of measured positive or negative fluid balance. The volume of fluid lost from emesis or diarrhea is estimated and recorded in the output column on each occasion. In the lower right-hand corner of the sheet, there is a line provided for the entry of the patient's weight in kilograms. When a patient is weighed, the resident-in-charge supervises, and the weighing is done at the same time and under the same conditions every morning. By utilizing the above information, one has a more accurate guide as to the status of the patient's fluid balance.

There are four columns on the right portion of the fluid balance sheet that are used to record the determinations for urinary specific gravity, chloride, and pH and for blood hematocrit and hemoglobin. The last column is reserved for determinations that may be ordered frequently throughout the day. The reverse side of this sheet serves as the nursing note form. An effort has been made to simplify nursing notes. Many routine nursing procedures that were formerly charted have been discarded; only essential facts are recorded.

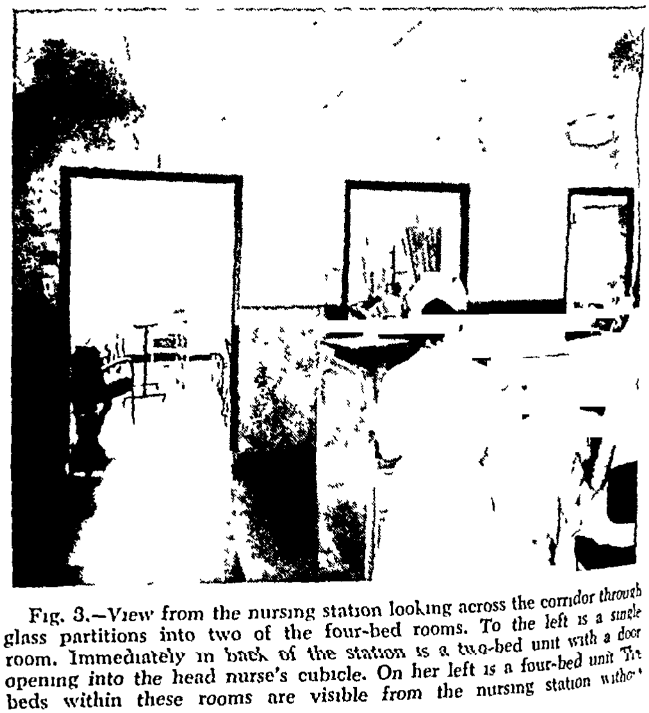

Fig. 3.—View from the nursing station looking across the corridor through glass partitions into two of the four-bed rooms. To the left is a single room. Immediately in back of the station is a two-bed unit with a door opening into the head nurse's cubicle. On her left is a four-bed unit. The beds within these rooms are visible from the nursing station witho entering the rooms.

For those patients who present problems in electrolyte balance, a form was designed to represent graphically the fluctuations from one determination to another. Different colors are used to denote each type of ion. With this chart it is possible to record accurately serum Na^+, K^+, Cl^-, and CO_2 findings on the particular day they were obtained. Such a sheet obviously would be needed only in exceptional cases. It is not intended to serve as more than a recording device to depict, in a more graphic fashion, fluctuations of serum electrolytes from their normal levels. The fact is stressed at all times that intelligent electrolyte therapy is predicated on a knowledge of the volume and source of fluid loss as well as the volume and content of administered fluids. Three horizontal columns have been incorporated at the bottom of this sheet in which the blood and plasma volume excess or deficit and blood urea nitrogen results may be recorded.

Two additional forms have been designed that aid in the recording of vital statistics of this unit. A special care sheet that summarizes the pertinent data regarding the patient's stay and course is printed on green paper and incorporated in the chart. This makes for ready identification of the chart in the record room. To insure against loss of records for statistical study, a large log book is kept on the unit. Upon the admission of a patient, the name and pertinent data relative to the patient are recorded. On discharge, the remaining data are entered by the resident in charge of the unit.

Selection of Patients

All emergency patients, such as those with active gastrointestinal bleeding or severe burns, may be admitted directly to the special care unit at the discretion of the resident-in-charge. All patients leaving the operating room who require special observation for variable periods of time, on the recommendation of the surgeon and the anesthetist, may be sent directly from the recovery room to the unit. As a rule, this has been anticipated, the units have been notified in advance, and the bed that the patient formerly occupied has been given up. The patient who has had a routine gastrectomy may remain in the unit for two or three days. Patients who have undergone heart or lung surgery may remain five to seven days. Those who have had certain types of gallbladder surgery may require one or two days of observation. Patients with severe burns frequently require more prolonged care. Some patients who are not necessarily critically ill but who are in potentially dangerous situations may be kept here for close observation. Those with chronic conditions are not admitted to the unit.

The resident-in-charge is vested with a considerable degree of authority in deciding when special care is no longer required. Since he is there at all times, he can best decide which patients may be moved to regular quarters. As a matter of courtesy, he is expected to speak to the visiting surgeon before actually moving his patient. The final decision regarding admission or discharge is vested in the chief of surgery, but so far this authority has not been exercised because of the fine cooperation of all surgeons, who have not abused the privileges of this excellent unit.

Administration of the Unit

Two committees have been organized that may be described as a higher and a lower echelon committee. The higher echelon includes the hospital director, the director of nurses, chief of surgery, and chief of anesthesiology. This committee functions when policy problems must be decided and also gives the much needed authority for the lower echelon, or working, committee. The lower echelon committee is made up of one member of the surgical service as chairman, one member of the department of anesthesiology, the senior surgical resident, the special care resident, the chief of the nursing service, the director of records, and one member of the administration. Every two weeks this committee makes rounds on the unit and holds a conference to ensure that the ideas and philosophy of the special care unit are being put into effect. At this time, a frank discussion is held so that any mistakes or differences can be rectified and suggestions made for improvements. Thus, we are able to meet at frequent intervals with persons from all departments that have to do with the care of the patient. Even after the short period of time that this system has been in effect, it is obvious that it is an ideal method for a more complete understanding of all people involved.

Summary and Conclusions

The shortage of nursing personnel has become a serious problem to the extent that, in many instances, the critically ill surgical patient is suffering from inadequate and inefficient care. Segregation of all critically ill surgical patients in a single area of the hospital staffed by nurses especially trained accomplishes the following things: 1. Expert care is guaranteed to those who need it the most. 2. The pressure is relieved in all other areas, lessening the need for graduate nurses and allowing for a more generous use of auxiliary help. 3. The demand for private nursing care for the individual patient is lightened. A special care unit at Rhode Island Hospital has been our method of converting this philosophy into actual operation. Our experience has convinced us that a special care unit for surgical patients is one solution to the serious nursing problem that faces us today.

Meconium Ileus.—Primary side-to-side ileotransverse colostomy and complementary proximal Witzel ileostomy is to be recommended in the treatment of meconium ileus. The more obvious advantages of this operation are as follows: 1. It is a single-stage procedure. 2. Immediate restoration of intestinal continuity is afforded. 3. Immediate decompression of obstructed intestine is permitted. 4. A means of irrigation is provided by which pancreatic enzymes may be used to liquefy and remove the obstructing, abnormal meconium. 5. No intestinal resection is done, nor does one seem warranted, considering that no lesion intrinsic to the intestinal wall exists. 6. There is reason to believe that the terminal ileum and right colon do not remain defunctionalized but rapidly take on their duties when the side-tracking anastomosis is no longer activated by distal obstruction. 7. The disadvantages of a double-barrelled skin ileostomy, no matter how brief and how minimized, are averted.—T. D. Throckmorton, M.D., and Philip M. Porter, M.D., Treatment of Meconium Ileus by Ileotransverse Colostomy, *A.M.A. Archives of Surgery*, June, 1956.

DIAGNOSIS OF CONGENITAL DYSPLASIA OF THE HIP IN THE NEWBORN INFANT

Sherman S. Coleman, M.D., Salt Lake City

• *Actual dislocation of the hip, with the femoral head lying completely out of the acetabulum, seldom exists at birth. It develops as a gradual process that should be watched for throughout the first year of life in every child. The possibility of recognizing at birth the dysplastic hips that will progress to subsequent dislocation was investigated by (1) examining 3,500 newborn infants specifically for skeletal deformities and (2) securing pelvic roentgenograms from 150 unselected newborn infants for a study of normal dimensions, averages, and ranges. It was found that in the newborn infant the usual physical criteria (such as unilateral shortening of the extremity) for the diagnosis of congenital hip dysplasia are inadequate and unreliable and that discrepancies between the clinical and the x-ray findings (such as a high acetabular index) were distressingly frequent. Congenital hip dysplasia was diagnosed in 32 of the 3,500 infants. It is impossible as yet to tell which joints will become stable spontaneously, which will persist as subluxations, and which will progress to frank dislocations. Since the treatment is simple, it should be applied in all cases that suggest a hip dysplasia.*

The tragedy of late diagnosis of the sequelae of congenital dysplasia of the hip is apparent in any children's hospital. At the Primary Children's Hospital, I examined 3,500 newborn infants during a period of 10 months. This report presents my observations and conclusion that diagnosis of dysplasia of the hip in the newborn infant is possible in the majority of cases. Since it is common knowledge that the earlier the treatment can be instituted, the better are the results, it logically follows that, if the diagnosis can be made at birth, treatment could begin within hours or a few days thereafter. In order to make such a diagnosis, every newborn infant should be given "the dignity of one thorough orthopedic examination."

Each resident who has served at the Latter-Day Saints Hospital has recorded his observations on newborn infants under his care, and I have had access to their data. Thus, records covering more than 11,000 examinations of newborn infants have been available. In analyzing the statistics, it was observed that a wide difference existed from one year to the next in the number of congenital hip dysplasias reported. It became apparent that discrepancies existed, either in the method of examination, in the criteria for diagnosis, or in the terminology employed by different examiners. As the study progressed, further questions arose as follows: What is a dysplasia of the hip in the newborn infant? Can the diagnosis be made at birth? If so, with what degree of accuracy? Of what significance and how reliable is an x-ray examination of the pelvis at birth? Finally, how many dysplastic hips are passing unnoticed during the precious months of rapid and impressionable growth of the pelvis? An attempt has been made in this study to set forth criteria for the diagnosis of dysplasia of the hip in the newborn infant and also to suggest answers to these questions. It is hoped that it may contribute to the knowledge of dysplastic hip disease and provide an aid to those entrusted with the early examination and care of these children.

Definitions

Throughout this report terms will be used that require clear definition for the purpose of discussion. These are dysplasia, subluxation, and dislocation (luxation) of the hip. The term congenital hip dysplasia was introduced by Hilgenreiner[1] in 1925. It is a general term denoting, as Gill[2] described, delayed or defective development of the hip joint and its associated structures. In this regard, it may be considered a precursor to the clinical entities of subluxation and dislocation of the hip.

The terms subluxation and dislocation of the hip are used similarly to that outlined by Putti.[3] In a subluxated hip the cartilage of the acetabulum and the femoral head are in contact; however, there is an abnormal relationship between the two. The term hip dislocation (or luxation) refers to a condition in which the cartilage of the acetabulum and the femoral head are not in contact, and the head lies completely out of the acetabulum.

Material and Methods

In the case of examinations covering 3,500 newborn infants, each was examined specifically for skeletal deformities existing at birth. With few exceptions, all infants whose physical examinations suggested the possibility of a congenital dysplasia of the hip had pelvic x-rays. Thus, a correlation between the clinical findings and x-rays in 27 cases in which there was presumptive diagnosis of dysplasia of the hip was made possible.

In order to establish more clearly the normal x-ray picture of the newborn infant, pelvic x-rays were taken of 150 consecutive newborn infants, unselected except on the basis of parental consent. The technique employed in making the x-ray picture was carefully designed, and I personally positioned and x-rayed each infant. As noted by previous investigators,[4] the position of the infant during radiography influences the x-ray picture; therefore, several infants were x-rayed in different positions and their measurements and findings were compared. This was done in order to determine the position that provides the most accurate and consistent results, with the least likelihood of error. The position agreed upon is basically similar to that employed in other studies. It is described and illustrated in figure 1. A true anteroposterior view of the pelvis is made, care being taken to eliminate possible errors from rotation, pelvic tilt, or parallax.

From the Primary Children's Hospital. Dr. Coleman is now from the Department of Orthopaedic Surgery, Northwestern University, Chicago.

The acetabular index was then measured, and the values encountered in these otherwise clinically normal hips were recorded and the average value was computed. High and low values were also recorded. Additional observations were made concerning the integrity of Shenton's line, the depth of the acetabulum, and the relationship of the femoral neck to the acetabulum according to the "H" line. These observations are summarized in the discussion that follows. In all cases a correlation between the x-ray findings and the physical findings was recorded. In the 27 newborn infants with dysplasia of the hip, similar observations were made, and the data concerning their acetabular indexes were recorded. Nine premature infants were included in the study in order to compare the x-ray appearance of their pelves with those of full-term infants.

Observations

Physical Findings.—The criteria initially employed by me to establish the diagnosis of congenital hip dysplasia by physical examination were those usually listed. These included limited abduction of the flexed hips, increase in depth or asymmetry of inguinal or thigh skin folds, unilateral shortening of the extremity, palpable abnormalities about the hip, and Ortolani's[5] "sign of the jerk." A careful attempt was made to elicit each sign. As the investigation proceeded, it became clear that most of these findings were rarely present in any infant. The impression was gained that, in the newborn infant, the usual criteria for the diagnosis of congenital hip dysplasia are inadequate and unreliable. Most of the conventional signs are late developments, occurring secondarily to progression of the dysplasia into a subluxation or a true dislocation of the hip. An analysis of each physical sign, along with my observations, follows.

Significant persistent limitation of abduction of the flexed thigh in the newborn infant is uncommon, and when it is present it is difficult to evaluate early because so often it is equivocal. Almost all infants can easily abduct their thighs to 80 degrees, and in some they can be abducted well beyond 90 degrees. For evidence of hip dyplasia in the newborn infant, reliance simply on limitation of abduction of the hips gives the observer a false sense of diagnostic security. In only 3 of 30 cases diagnosed as dysplasia of the hips in this study, the infants exhibited limitation of abduction of the flexed thigh. In one of these it was equivocal. On the other hand, in three infants with the most pronounced dysplasias, the hips were capable of being abducted easily beyond 90 degrees. Well over one-half of the cases diagnosed by me were overlooked by the initial examiner because of the conspicuous absence of limited abduction of the hips.

In the newborn infant, absence of limited abduction in hip dysplasia is understandable. In the first place, the joint at birth is seldom truly dislocated[6]; rather, it is merely unstable, having either a capsule that is excessively lax or a socket of inadequate depth, or both. None of these conditions can logically explain limitation of abduction. In the average case of congenital dysplasia of the hip, it is usually as the condition progresses to a true subluxation or dislocation that persistent contractures of the adductors take place.[7] This is probably a gradual, insidious process and should be watched for throughout the first year of life in every child.

The skin folds of a newborn infant are difficult to interpret, and, even at best, asymmetrical skin folds are only suggestive. At birth there is a normal "springy" tightness of certain muscle groups, particularly the hip flexors. This tightness is often slightly asymmetrical. It is physiological during the first few weeks of life, and it can be traced in part to the flexed position of the hips in utero. Howorth[8] suggests that this infantile hip-flexion contracture is a phase in the normal development of the hip joint as it passes from the flexed to the extended position. Certainly such variable factors influence the formation of skin creases, making them diagnostically unreliable. In the presence of mild asymmetrical flexion contractures in the newborn infant, particularly in the absence of other findings, skin creases are virtually meaningless.

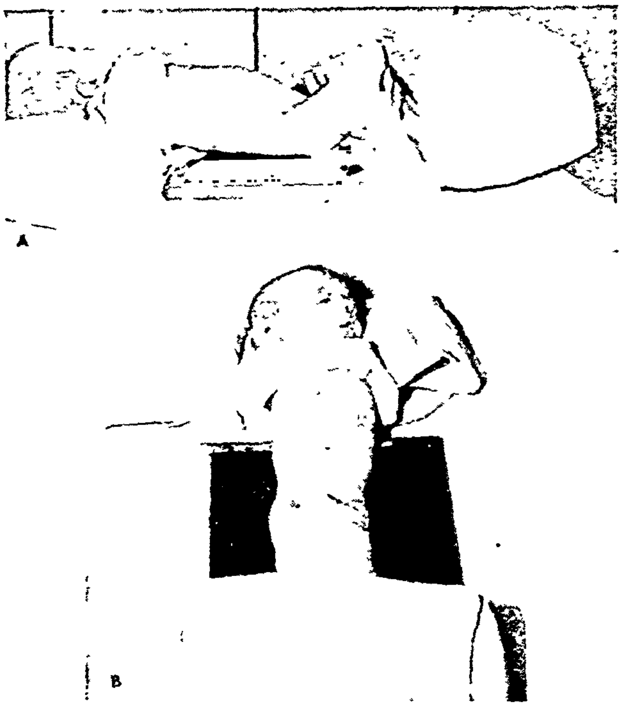

Fig. 1.—*A*, side view of infant in position for x-ray. Lower extremities are wrapped in an Ace bandage with patellae facing anteriorly. Legs are held in parallel alignment by means of pad between legs. Legs are placed on one sandbag 2 in. high, which allows controlled amount of flexion at hips. Another sandbag lies on top of legs to hold them firm. Each arm is restrained with a sandbag. X-ray tube is centered over symphysis pubis. *B*, front view, showing method of restraining infant and position of child on cassette. Rotation is the only variable to control.

Regarding true unilateral shortening of the extremity, in this study, it was not discernible on any of the newborn infants having a diagnosis of dysplasia of the hip. The explanation for this again lies in the important observation that the hip joint is rarely dislocated at birth. At least this obtains in the cases not associated with multiple deformities of the type that Hass[9] and Badgley[10] call "teratological." It is true that complete dislocation of the hip has been reported in a 5-month fetus,[10] and a rare few cases are recorded of infants having dislocated hips at birth; however, in nearly every case of simple congenital dysplasia of the hip, the femoral head is not dislocated in the newborn infant. Thus, true shortening of an extremity is rarely encountered at birth, and, by the same token, palpable abnormalities about the hip joint were not found except those incident to eliciting the "jerk of exit and entry."

The jerk of entry was described by Ortolani [5] in 1935. This consists of a palpable jerk incurred as the subluxated or dislocated hip is reduced into the socket by abducting the flexed thigh and levering the femoral head into the acetabulum. Following this procedure, if the thigh is adducted, the head slips out over the posterior acetabular rim, producing a jerk of exit. This sign is best elicited in the later months of infancy when the secondary signs of hip dysplasia, particularly early dislocation, have occurred. In the newborn infant, however, since dislocation or significant subluxation of the hip rarely exists, Ortolani's maneuver, as described above, cannot be performed. Rather, the reverse of this maneuver must be executed, that is, a jerk of exit must initially be sought.

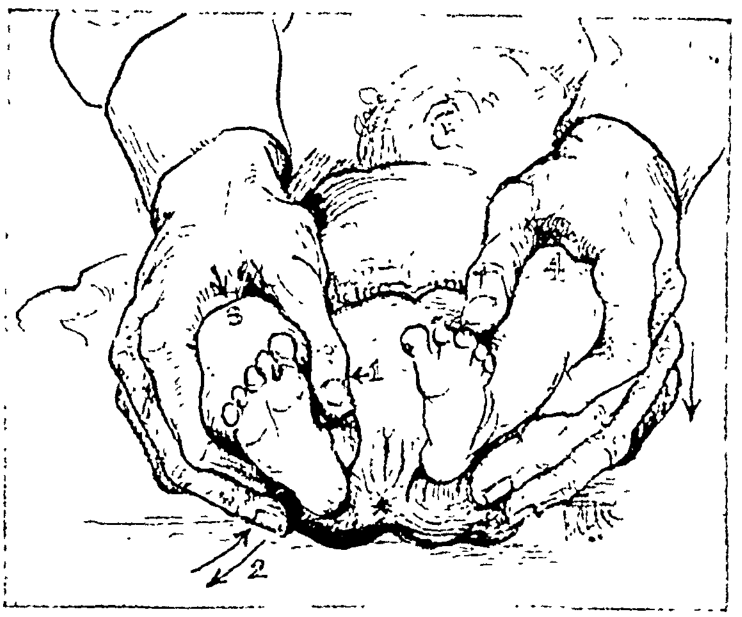

Fig. 2.—Method of examination. One hand steadies pelvis by firmly grasping knee (4) of one leg and exerting downward pressure on the flexed thigh. The other hand grasps the opposite extremity as follows: The fingers overlie the greater trochanter (2), and the thumb is placed over the medial aspect of the upper thigh near the inguinal crease (1). This provides firm grip on the proximal end of the femur. Employing the knee as a fulcrum (3), posterolateral force (arrow) is gently exerted on the upper end of the femur in an attempt to displace the femoral head.

This jerk of exit can be demonstrated as a very definite palpable and sometimes visible displaceability of the femoral head as it passes over the posterior rim of the acetabulum, into a temporarily subluxated position. It is not merely a snapping sensation. Many infant's hips exhibit palpable snaps with the slightest manipulation into the frog position, but it is likely that these are normal ligamentous and capsular phenomena. It was my observation that, in the newborn infant, the jerk of exit is the principal reliable physical finding that suggests a hip dysplasia. The displaceability can be elicited in most cases only if carefully sought. This requires a gentle, well-controlled attempt to displace the hip laterally or posteriorly; this was the technique adopted in this study. There is no undue force exerted, and no attention is paid to the commonly felt snapping phenomena. The hips are flexed and slightly abducted. The pelvis is fixed on the one side by vertical pressure on the thigh while the examiner gently tries to displace the femoral head on the opposite side (fig. 2). In order to be considered positive, palpable displaceability of the head of the femur must take place. As there is some variation in the ease with which the femoral head can be displaced, it is likely that the easier the displacement occurs, the more shallow is the acetabulum and the more severe the dysplasia.

The anatomic factors that may permit this to occur have been mentioned earlier. These are excessive laxity of the capsule and ligaments of the hip and unusual shallowness of the acetabulum, particularly its posterior portion. Howorth [8] suggests that capsular laxity is the principal fault that initiates the chain of events leading to dislocation of the hip. Ortolani,[11] on the other hand, found in studying three fetal dislocations at autopsy that deficiency of the posterior acetabular rim is the major fault. It is concluded from this study that both conditions play a role in the pathogenesis of hip dysplasia in the newborn infant. Capsular laxity is certainly not the only factor, as evidenced by the occasional infant in whom excessive hip-joint motion is exhibited but in whom there is no demonstrable displaceability of the femoral head. From observations in this investigation of exclusively clinical material, it is concluded that shallowness of the acetabulum, particularly its posterior portion, must be the principal defect in the newborn infant and that capsular laxity may or may not coexist. Evidence for this defect, in the form of displaceability of the femoral head from the socket, must be sought for in every newborn infa by the maneuver described above. When present, presumptive diagnosis of dysplasia of the hip can b made.

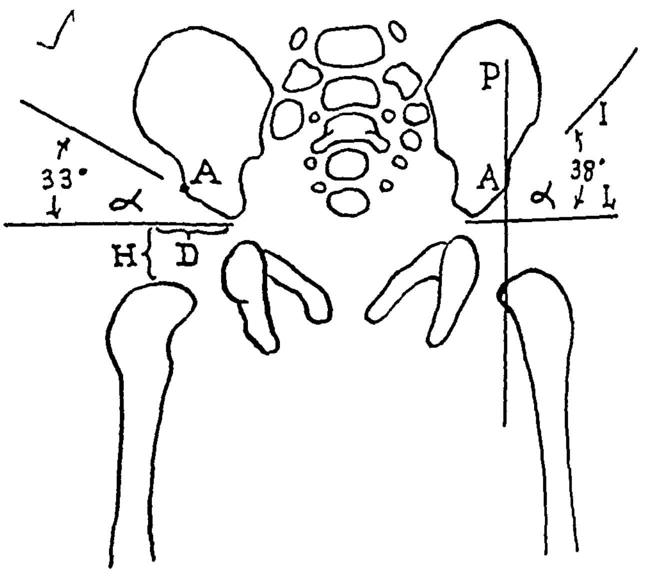

Fig. 3.—Drawing from roentgenogram of pelvis of newborn infant. (Th infant's hips were normal on physical examination.) "A" indicates anter inferior iliac spine; "L" is horizontal line of Hilgenreiner, drawn throu comparable points on triradiate cartilage; "I" is line drawn parallel t acetabular roof; angle formed between "I" and "L" is acetabular index, "P" is Perkins' line, a perpendicular dropped through anterior-infe iliac spine at right angles to "L"; "H" is distance between "L" and hi point on femoral neck; and "D" is distance between triradiate cartilage intersection of "H" and "L."

X-Ray Findings.—One of the distressing observatio made early in the study was the discrepancy betwe x-ray findings and the clinical findings, this being p ticularly true concerning the acetabular index. Th index is the angle that the slope of the acetabular ro makes with a horizontal line drawn through comparable points on the triradiate cartilage (fig. 3). Hilgenreiner[1] drew attention to the possible diagnostic significance of this angle in 1925. Kleinberg and Lieberman,[12] on the basis of x-ray examinations of 23 newborn infants, concluded that an acetabular index above 30 degrees at birth suggested a potential dislocation of the hip. They also determined the average index to be 27.5 degrees. In this study of 300 clinically normal hips, these values were not substantiated. Significantly higher values were obtained, showing that 30 degrees, rather than being the upper limit of normal, is about the average for newborn infants. Brewer[13] and others concur in this observation.

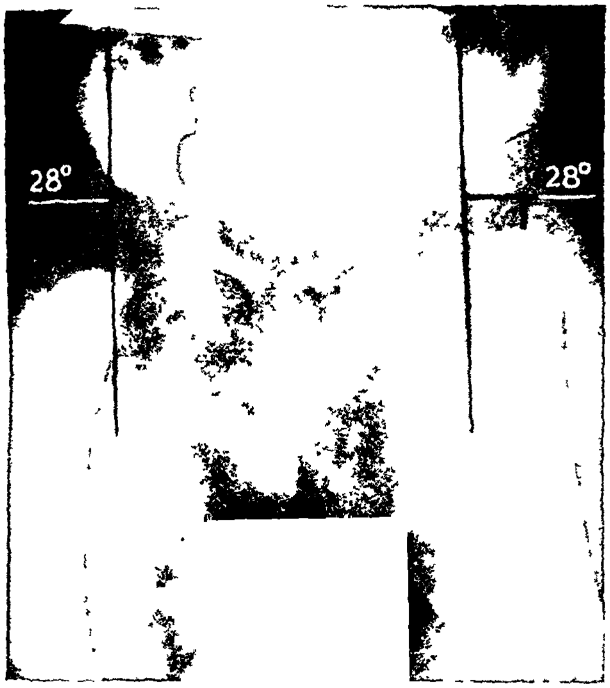

Fig 4.—Pelvic x-ray of newborn female infant having displaceability of the left hip on physical examination. Acetabular indexes are equal, being below average. Lateral disposition of left femoral neck is apparent, as is significant discrepancy in Hilgenreiner's "H" and "D" lines. In this case there is some alteration in Shenton's line on affected side

A wide range of measurements was recorded, varying from 20 to 42 degrees. The mean was computed at 30.86 degrees. The standard deviation was 3.8 degrees. Lower and upper limits of normal ranged from 23.3 to 38.5 degrees (95% of normal hips should fall within this range). The range of values and the number within each range of the 300 normal hips are as follows: 20-21 degrees, 2; 22-23, 5; 24-25, 24; 26-27, 25; 28-29, 44, 30-31, 68; 32-33, 53; 34-35, 54; 36-37, 14; 38-39, 9, 40-41, 1; and 42-43, 1. An interesting finding concerns the measurements of the acetabular indexes in nine premature infants, born between seven and eight and one-half gestational months. No significant difference was noted between the average indexes of these infants and those of full-term babies. In fact, the only difference was that the premature infants exhibited values more uniformly around 30 degrees. The range of values and the number within each range for these 18 hips are as follows: 24-25 degrees, 2; 26-27, 4; 28-29, 4; 30-31, 2; 32-33, 1; 34-35, 2; 36-37, 2; and 38-39, 1. The mean value was 30.2 degrees.

Additional observations were made relating to the sex of the infants and their height and weight. A slight increase in the average acetabular index was noted in females as compared to males. This was, however, not statistically significant. No reliable correlation could be drawn between the size of the infant and the acetabular index. This is understandable, for the acetabular index appears to be only a measure of the degree of ossification of the roof of the acetabulum. It does not necessarily reflect skeletal size.

Thirty babies were considered to have congenital dysplasia of the hip by physical examination. X-ray examinations were made of 27. Sixteen had bilateral dysplasias on physical examination; thus, there were a total of 43 clinically abnormal hips. The acetabular index was measured in each abnormal hip. The range of values extended from 28 to 49 degrees, and the average index was 36.5 degrees, showing that, in these abnormal hips, the average index was 6 degrees higher than values encountered in the series of normal hips. The range of values and the number within each range for 43 clinically abnormal hips are as follows: 28-29 degrees, 4; 30-31, 7; 32-33, 4; 34-35, 4; 36-37, 4; 38-39, 6; 40-41, 5; 42-43, 4; 44-45, 1; 46-47, 3; and 48-49, 1. On the basis of the values computed above on the clinically abnormal hips, it is noteworthy that only 14 out of 43, or 33%, exhibited values significantly above the normal range. The suggestion is, therefore, that the acetabular index shows diagnostic correlation in only one-third of the clinically abnormal hips examined radiographically.

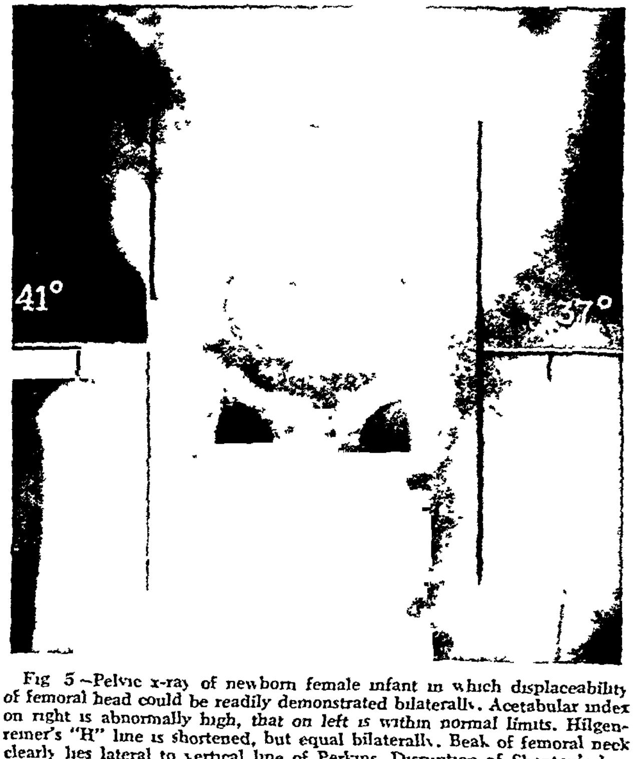

Fig 5.—Pelvic x-ray of newborn female infant in which displaceability of femoral head could be readily demonstrated bilaterally. Acetabular index on right is abnormally high, that on left is within normal limits. Hilgenreiner's "H" line is shortened, but equal bilaterally. Beak of femoral neck clearly lies lateral to vertical line of Perkins. Disruption of Shenton's line is equivocal.

In evaluating other radiographic features of the dysplastic pelvis of the newborn infant, variations were encountered but no single deviation was consistently found. Shenton's line is very difficult to ap-

OLD PROBLEMS AND NEW CHALLENGES IN MEDICAL EDUCATION

Edward L. Turner, M.D., Chicago

• *There is need for continuous revision of curriculum, techniques, and methodology in medical education. Examples of current problems are the increasing amount of specialization, the decreasing number of patients who are wards of the public, and the chaotic state of postgraduate education. Programs instituted in the name of correlation and integration must be reexamined often to make sure that the intended results are achieved. Teaching and research are copartners when they are well balanced, but teaching must not be allowed to become an incidental matter, for research in itself cannot supplant the need for continuous study and preparation for teaching. The recruitment of basic scientists has become an important administrative problem. No single formula will solve all these problems, but it is important to remember that medical education involves the teaching of individuals who are destined to care for other individuals, and that its prior task is to inspire.*

"Times and men and circumstances change about your changing character with a speed of which no earthly hurricane affords an image. What was best yesterday—is that still the best in this changed theater of tomorrow? Will your own past truly guide you in your own violent and unexpected future?" These words written by Robert Louis Stevenson aptly portray this dynamic, exciting, and uncertain period of history and suggest the eternal challenge of preparing to meet the needs of today and of the tomorrow that lies ahead. No phase of human endeavor can be described as static in the current scene. The ever increasing scientific knowledge associated with these changes in "time and men and circumstances" has made many traditions, tools, and techniques adequate and effective yesterday now inadequate and obsolete in meeting the challenges of today or in preparing for those of the future.

The past half-century has witnessed enormous advances in scientific knowledge applicable to medicine, which have been reflected by significant changes in medical practice. They have necessitated marked readjustments in medical education. No one can be clairvoyant in regard to the future when knowledge is advancing at such an unprecedented rate. An effort to discuss and reemphasize some of the challenges in medical education that lie ahead may seem almost foolhardy when events are taking place with such acceleration. Old problems present new angles, and new challenges appear on every side. My position is somewhat like that of a student in one of Prof. William Lyon Phelps' classes some years ago. At the end of a pre-Christmas examination, this student handed in a paper on which he had written, "God only knows the answer to this question. Merry Christmas." Professor Phelps returned the paper with the notation: "God gets an A; you get an F. Happy New Year."

Background Preparation

Some of the problems giving concern to medical educators today are more fundamental than the problems of medical education itself. They extend into the area of education prior to admission to medical school and include the question as to just what constitutes the most desirable background preparation. A quarter of a century ago, emphasis was well nigh exclusively directed toward the scientific aspects of premedical education, almost to the point of exclusion of social sciences and the humanities. Since physicians deal with people and should be in the best possible position to understand them, many educators in the field of medicine felt that a more balanced educational background was needed. This soul-searching resulted in a gradual swing of the pendulum toward the concept of a broad, general education as the most desirable background for a physician.

Such a background is a highly desirable possession for any individual regardless of his sphere of activity. However, at the present time, when scien-

tific advances are being made more rapidly than ever before in history and when a solid scientific knowledge is more important than ever, there is also increasing concern over those areas of education that do not fall under the classification of the natural sciences. Just what is meant by a broad, general education? Just how significant is breadth unless there is also a degree of depth? How can the background of the student preparing for medicine be adequately scientific and also include a broad interest in and full appreciation of the socioeconomic facets of human interrelationships? How can we avoid the type of premedical pattern that would tend to stereotype background preparation for a field that offers such a variety of opportunities as are inherent in medicine?

Undoubtedly, one of the keys to this dilemma lies in the development of better intercommunication and closer cooperation between those responsible for medical education and those responsible for preparing students for it. Individuals advising and guiding potential medical students through their college years will be in a position to be of maximum assistance if they fully appreciate the objectives of medical education and the background experiences deemed most helpful in achieving them. It would seem that medical educators have a direct challenge to assist in bridging this academic gap more effectively to the mutual advantage of all concerned.

Undergraduate Education

At the turn of the century, the basic objective of undergraduate medical education was to prepare the student to enter practice. Today, the basic objective of undergraduate medical education is to aid the student in laying the foundation upon which he may build further experience, directed toward certain goals, prior to the initiation of practice. Thus, undergraduate medical education currently plays the role of partial, rather than total, preparation for professional life. How can this partial preparation be made most effective so that it will serve as a suitable foundation for the area of practice, teaching, or research that its possessor will subsequently develop?

This age of specialization has been described by some serious writers as an age of isolation marked by competition between specialists who tend to maintain a laissez-faire attitude toward others. Such an attitude, in turn, lessens the sense of obligation to cooperate and, at times, seems to foster an unwillingness to share in the complex problems of a total group. Sometimes specialists, while working to the best of their ability and aiming at the optimum performance of their own tasks, may find that their actions are determined by thinking and action that are unrelated to each other. I would be willing to offer a substantial wager that every dean has encountered situations of this type in the course of his routine administrative responsibilities. How, in any one given situation, can responsible medical educators overcome this facet of specialization that it has helped to create? This is important if the basic foundation that is to be erected during undergraduate medical education is designed so that its partial role in the total development of the physician will be of maximum value, regardless of the ultimate direction of practice, teaching, or research. What is the best way to coordinate an educational experience in specialist environment so as to develop an educational opportunity that will not lack human and social direction? How can educational programs in medicine be planned so as to offer an all-embracing opportunity for the development and full appreciation of the medical and social problems of patients and maintain intellectual, emotional, social, and technological components in reasonable balance? What are the best approaches in a given medical school environment to insure the development of and to maintain the teamwork necessitated by specialization and avoid the trend toward the increasing impersonalization inherent in fragmentation? These are questions of serious nature that require study, planning, and suitable action if the partial role of undergraduate medical education is to be made the substantial foundation for graduate and continuing medical education that it should be.

Traditional Patterns in Education

Questions such as these can be answered and the problems they raise solved only if there is broad, general faculty appreciation of institutional objectives and the interdigitating functions of various departments in achieving them. Today, when knowledge is advancing so rapidly, there is need for constant study and almost continuous revision of curriculum, techniques, and methodology. However, tradition in medical education, as in many other areas, at times becomes a matter of real concern in efforts to make needed readjustments. Some individuals and some groups seem to forget that tradition is man made and that it should constantly be reevaluated and adhered to or discarded in line with fundamental common needs. Basically, there is nothing so good that it cannot be improved. Although there is much that is good in tradition and many traditions should be steadfastly cherished and fostered, they should not be permitted to stand in the way of sound progress. Years ago Nietzsche observed, "Every tradition grows more venerable—the more remote is its origin, the more confused that origin is. The reverence due it increases from generation to generation. The tradition becomes holy and inspires awe." Arnold commented, in more picturesque fashion, that he was "well satisfied that if you let in but one little finger of tradition, you will have in the whole monster, horns and tail and all."

The point in question is that traditional patterns in curriculum planning and the associated educational techniques and methods are difficult to readjust unless those who are charged with the responsibility of their organization and supervision are fully aware of the factors that require modification in light of the constantly changing scene. No one person in a medical school setting can effectively accomplish the creation of a new pattern for the over-all group. Only a representative group, cognizant of all facets of total curriculum content and with clear-cut objectives, can keep a medical curriculum dynamic and reasonably balanced. Additive material to be included within restricted time allocations necessitates intelligent alterations and subtraction of outmoded or less relevant data. During recent years additive material has accumulated at a rate more rapid than can be counterbalanced by the simple process of deletion alone. This necessitates consideration of ways and means whereby time allocations devoted to excessive or unessential detail may be modified in favor of developing sound concepts of general principles. However, the understanding of general principles necessitates certain basic factual knowledge.

Every responsible medical educator, therefore, constantly encounters the challenge in his own field as to the determination of what constitutes essential factual information and how it can best be utilized to aid in the development of the sound knowledge, understanding, and judgment desirable in the physician. This is where intelligent imagination assumes an importance almost as great as that of knowledge. Whitehead has pointed out, "Knowledge does not keep any better than fish," and that in "successful education there must always be a freshness in the knowledge dealt with." He furthermore indicates, "The properly trained man has some hope of obtaining an imagination disciplined by detailed facts and necessary habits," and this certainly should be one of the basic goals of sound medical education.

Correlation and Integration of Teaching

During recent years much has been said about correlation and integration of medical teaching. A good deal is being done in the name of correlation and integration that falls far short of actually accomplishing such results and tends to reduce the significance of these terms. Genuinely effective correlation and integration also necessitate full appreciation and understanding of the things that are being brought together as well as comprehension of the objectives being sought. Efforts along these lines require an open-minded approach to problems and a willingness to make effective adjustments without compromise on quality or achievement of objectives. Unless these efforts are designed to develop a better educational mousetrap and give fair promise of doing so, nothing of material value is accomplished. Some facets of medical education correlate or integrate with ease and effectiveness, while others present difficult and perplexing enigmas that almost defy other than isolated approach. Correlation and integration of certain aspects of medical education are means whereby some of the problems mentioned earlier in this discourse may be approached as well as effectively solved. However, no faculty should delude itself into the belief that such efforts are simple, for they involve careful background planning, discussion, and supervision when activated. The easiest and laziest way is to side-step such efforts and teach in the splendid isolation of specialization. This more traditional approach is time consuming, involving a great deal of duplication of effort on the part of both teachers and students that can ill be afforded.

Flexibility in Departmentalization

One of the major academic challenges and problems today is, therefore, to determine "how to make the ancient rigid framework of departmentalization serve the purpose of medical education in its true relation to biology and the basic sciences." [1] The challenge extends into the area of overcoming this rigid framework through reasonable flexibility or through the creation of a new framework susceptible to flexibility. Unfortunately, it is necessary to keep in mind that "broad philosophies are one thing, and pedagogic expedients another." It is stimulating to observe the increasing cooperation that is currently under way between departments in medical schools and between medical schools and other areas of academic discipline. The rigid framework of departmentalization has of necessity become more flexible with the realization that, in the current setting, no departmental discipline is sufficient unto itself. Basic sciences spill over into each other's domains and into almost every facet of clinical activity. Honest appraisal of any departmental discipline demonstrates that, if it were to be stripped of the knowledge contributed by other departments today, there would be little remaining but a ghost of the past.

Teaching and Research

Teaching and service were the two major component functions of medical education in the United States during the early years of the current century. There was little evidence of any real effort to advance knowledge in the majority of the medical schools of that period. However, at the time of the first serious survey of medical schools by the Council on Medical Education of the American Medical Association, one of the 10 criteria used to evaluate institutions rested in determining whether or not faculty members had made or were endeavoring to make original contributions to knowledge through research. Today, experimental investigation, or research, is universally recognized as one of the three major activities of a medical school. Deitrick and Berson [2] indicated that research "is the principle means by which the medical school fulfills its fundamental obligations for the advancement of knowledge." Research today necessitates a considerable portion of the faculty time in most institutions and has been associated with increasingly large financial support.

It is hardly necessary to remind you that teaching and research are co-partners where they are well balanced and each given its due emphasis. Actually, investigation in a research project and good medical practice are fundamentally kindred in spirit, method, and objective. In facing his responsibilities, the physician encounters the same type of challenges that confront the scientific investigator. Each patient is an individual presenting a problem that must be studied and analyzed, submitted to rational therapeutic procedures, and then followed to the point of satisfaction with the result of such analysis, conclusion, and action.

Physicians have need of the same type of alert, systematic, thorough, and critically open-minded approach that characterizes the research scholar. A medical school whose faculty personnel are not actively seeking answers to the myriad of unsolved problems confronting them would hardly be worthy of its name and would furnish a dull environment for both teacher and student.

Research, however, is a term that has been handled in recent years almost as loosely as coordination and integration and has played an even greater role in determining how faculty personnel utilize their time. The importance of research, with its potential and increasing impact on medicine as well as on human welfare, can be readily appreciated by surveying the procession of discoveries and the subsequent application of this knowledge that has occurred in recent years. It was to be anticipated, with the glamour and potential values now associated with the word research, that conflicts would inevitably arise in medical schools involving problems of balance between research and teaching functions. There is no denying the fact that in numerous instances research has overshadowed the total activities of some individuals with teaching responsibilities to the point where the latter have become an incidental rather than a major matter of concern. This is not in the best interests of medical education, for research in itself cannot supplant the need for continuous study and preparation for teaching. It cannot replace the lack of supervision when it becomes so time consuming that it sidetracks teaching responsibilities. It is important for medical faculties to remind themselves that the primary function of a medical school is to offer the learning opportunities and environment needed in the basic education of a physician. Good teaching, therefore, is of paramount importance; good teaching balanced with good research on the part of the faculty greatly enhances educational potential. The shirking of teaching responsibilities in the pursuit of research, real or fancied, cannot be condoned in the individual charged with teaching as a major obligation. This merely emphasizes that these two important functions of a medical school must each be given their due recognition and emphasis in keeping with the personnel, facilities, and financial resources available to the institution.

Problems of Administration

The problems and challenges that confront responsible administrators in this fascinating field of medical education become increasingly numerous and more complex as the scene changes. Those that have been presented represent only a few of the broad issues confronting all schools today. One matter of increasing concern lies in the relative dearth of manpower in the basic medical sciences. Recent years have witnessed the development of many new fields of scientific interest that are competing for top caliber youthful intellect. Economic competition for well-qualified young basic scientists has developed that is difficult for medical schools and their parent universities to meet effectively. Within medical schools themselves, there has been increasing competition for the basic scientists through their increasing utilization in clinical research programs. This increased utilization of the basic scientists in clinical investigation is to be highly commended and further encouraged. However, it is important that opportunities for teaching and research as well as economic reward be of such nature within the basic science areas themselves that they may remain virile and dynamic through attracting and retaining adequate personnel as well as through the development of personnel to meet needs in these other fields. Recruitment of personnel in these fields presents the administrative challenge of meeting more effectively some of the economic aspects of making such careers more attractive.

As has been indicated earlier, the rapidly changing socioeconomic pattern during recent years has had great impact on medical practice and has necessitated significant readjustments in both undergraduate and graduate medical education. The day is not long past when the great reservoir of patients ordinarily involved in medical education and training fell within the group of individuals known as wards of the public. In those days, most private patients or patients who covered part of their cost were considered as unavailable in a medical education program. Prepaid insurance and welfare programs have changed the traditional setting drastically in a relatively short period of time. The philosophy of medical education has of necessity undergone tremendous readjustment, necessitating recognition and acceptance of the fact that any and all categories of patients are suitable and available for participation in medical education programs if they are properly indoctrinated into its meaning and significance by their physicians. Thus, there is increasing incorporation of the private patient into undergraduate and graduate medical education in most institutions. Trends are sufficiently well established so that the time may not be far distant when all institutions must adapt their programs so as to utilize effectively the potentialities of the private patient and patients covered by one form or another of prepaid insurance.

Graduate and Postgraduate Education

This trend has, however, created problems in certain fields of graduate medical education that are not easy to solve effectively. How, for instance, is the surgical resident to receive preparation through the assumption of increasing responsibility on a service consisting primarily of private patients? Where does responsibility lie in such a situation, and how can it be solved to the mutual satisfaction of the patient, the resident, and the responsible residency supervisor? Answers to problems of this nature are being furnished in various ways in different institutions. The impression is gained that the need for working out satisfactory solutions to problems of this type has been beneficial in many ways, as it tends to curtail independent, unsupervised responsibility. The effective solution of problems of this nature actually holds promise of improving rather than weakening graduate education in the long run.

detectable clinically. This should prevent unnecessary opening of the chest for cardiac massage and other measures. The observer can initiate other measures to return the blood pressure to normal without loss of valuable time in trying to assure the correct diagnosis.

Ventricular Fibrillation.—During ventricular fibrillation, the heart muscle loses its power of effectual contraction and the various bundles beat independently and asynchronously in a fascicular type of activity. This results in failure of ejection of blood from the heart, with absence of pulse and blood pressure. During ventricular fibrillation, the galvanometer needle of the cardiac monitor produces very small, irregular, and highly erratic oscillations, completely lacking any rhythmicity. The baseline (isoelectric line) wanders throughout the range of the dial. Here again, the cardiac monitor duplicates the electrocardiographic pattern (fig. 2*D*).

Comment

The cardiac monitor was developed to allow continuous, instantaneous visualization of the electrical activity of the heart as an aid to the surgeons and anesthesiologists in a large general hospital. The device would be of even greater value in the small hospital or for use during dental anesthesia, when a qualified anesthesiologist is less likely to be available. The small size, portability, and self contained power supply of the monitor suggest its use in ambulances and by police and fire department rescue and resuscitation squads in cases of drowning, electrocution, vehicular accidents, and severe injury or illness. In civil disasters or combat situations, the availability of the monitor would facilitate sorting of living from dead casualties and resuscitation and treatment under very adverse conditions.

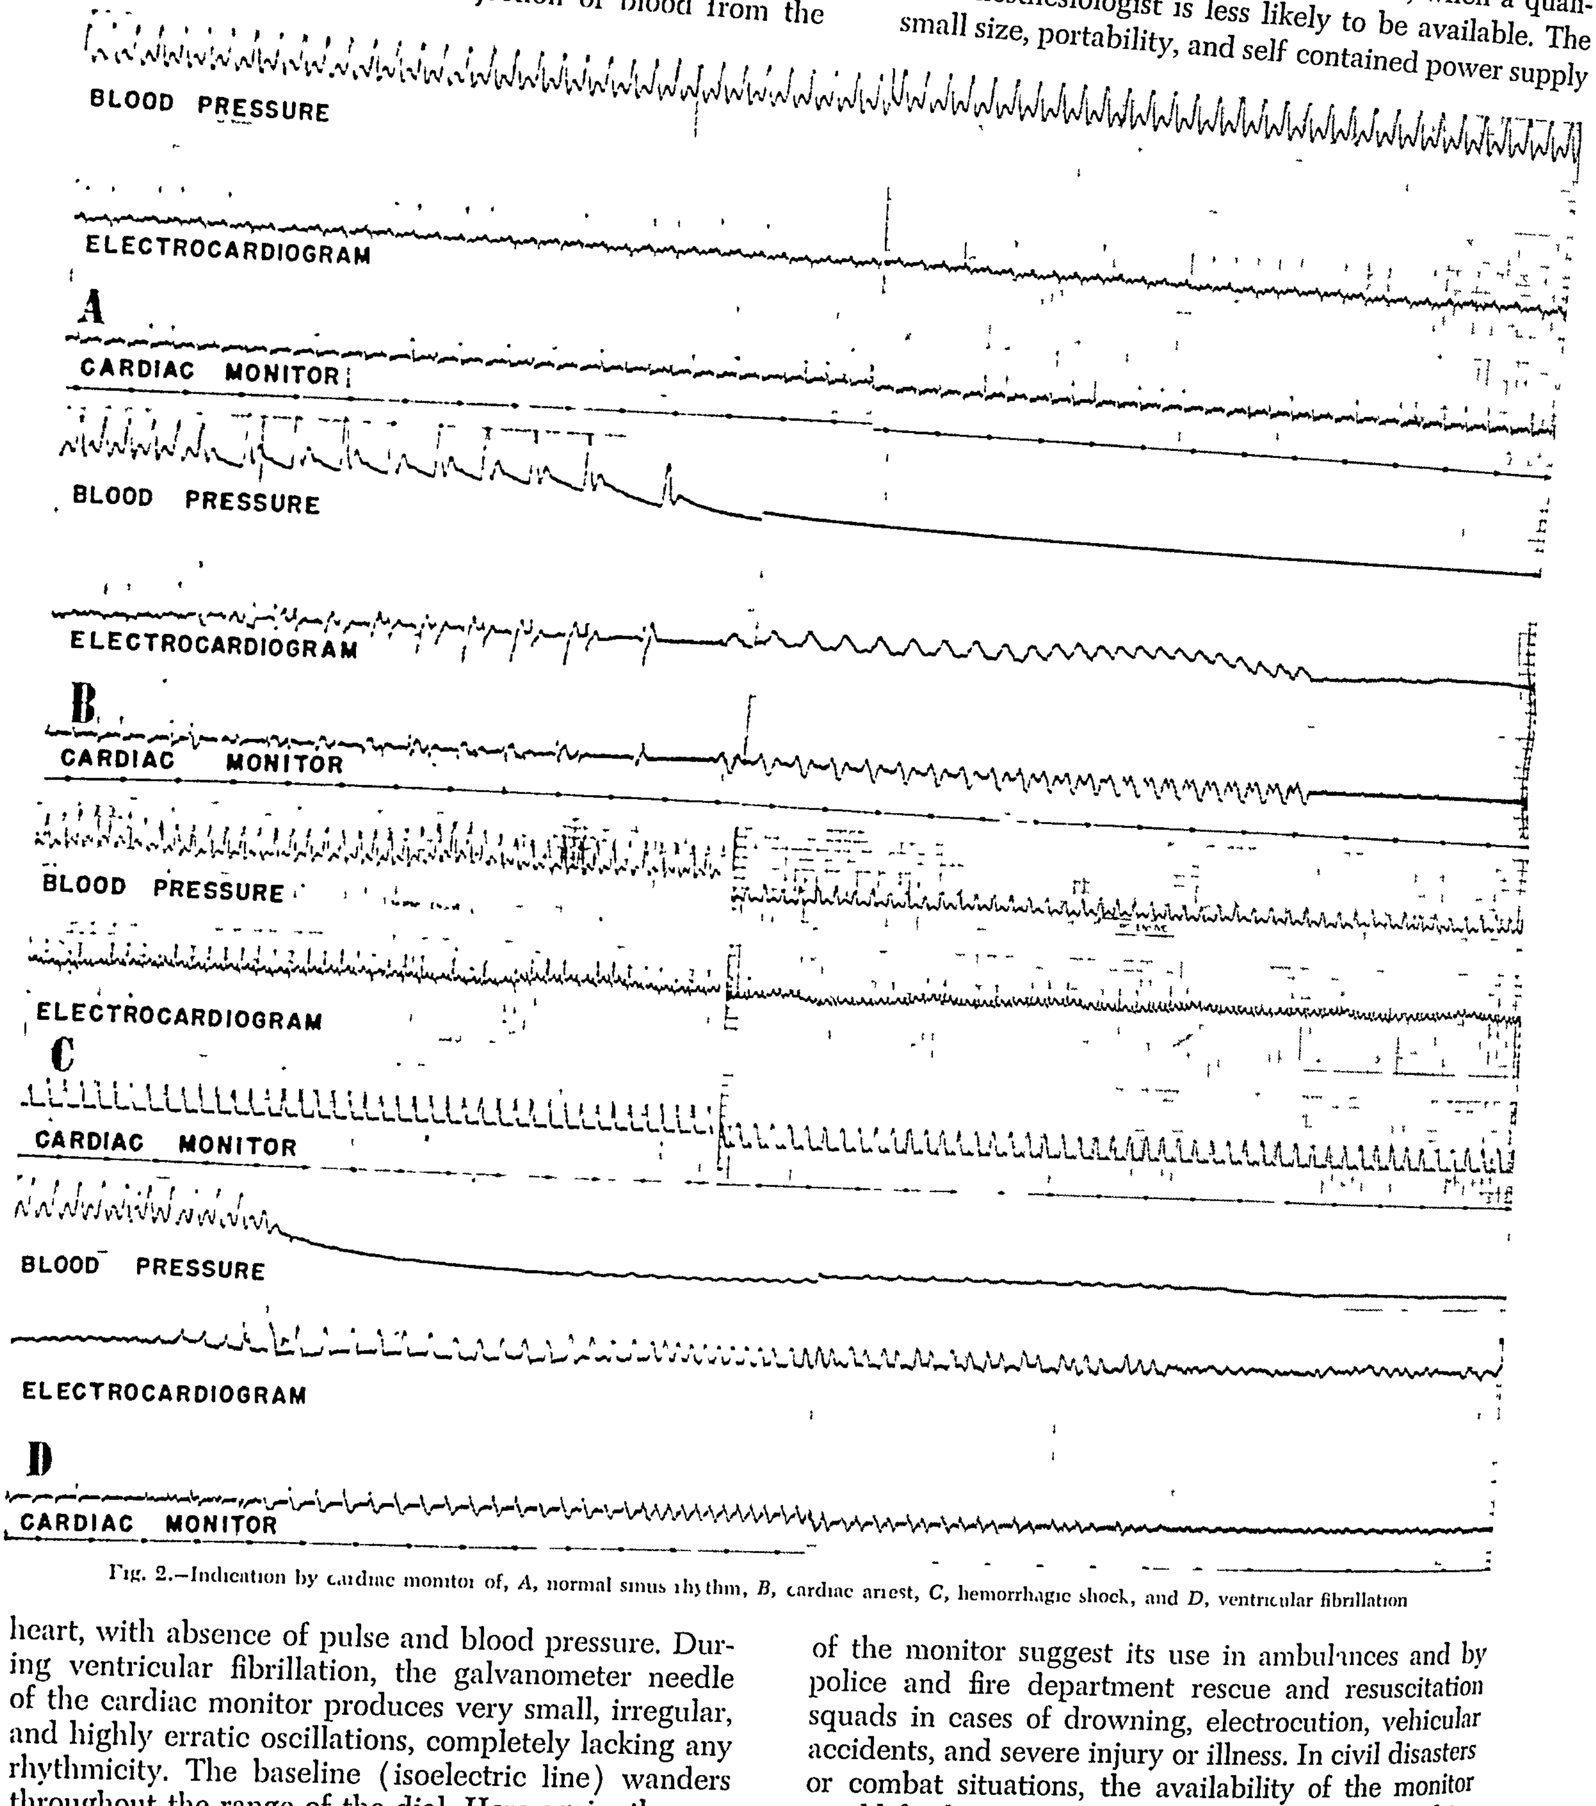

Fig. 2.—Indication by cardiac monitor of, *A*, normal sinus rhythm, *B*, cardiac arrest, *C*, hemorrhagic shock, and *D*, ventricular fibrillation.

Summary

The cardiac monitor is a portable, battery-powered electronic device for monitoring the electrical impulse of the heart. The amplifier is a multiple-stage transistor circuit, the output of which feeds a milliammeter and a headphone. Under normal conditions, and in cardiac arrest, shock or peripheral vascular collapse, and ventricular fibrillation, the monitor gives a characteristic, diagnostic response.

STUDY OF RESPIRATORY LIVER METABOLISM IN SURGICAL PATIENTS

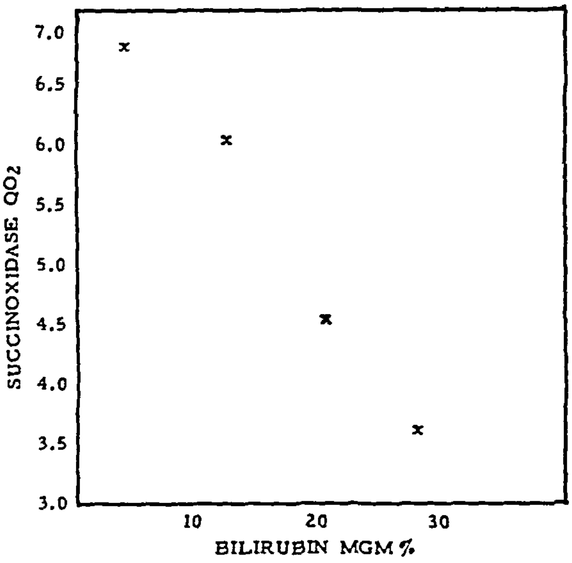
H. Clinton Davis, M.D.
Irwin S. Morse, M.D.
Edward Larson, Ph.D.
and
Mark Wynn, M.S., Miami, Fla.

The usual liver-function studies coupled with needle biopsy of the liver have been valuable in appraising liver disease. They permit an accurate appraisal of the pathology without an exploratory operation, and frequently they avert an unnecessary surgical procedure. Yet, the occasional poor correlation between the laboratory and pathological reports serves as a constant stimulus to develop new methods of research or to reapply older techniques for further biological information. Direct physiological tests on liver tissue have been used for many years in experimental work on small animals; however, relatively little work has been done on the respiratory metabolism of the human liver. The frequency with which liver biopsy specimens are taken at the operating table for pathological examination, and the benignity of the procedure, have prompted us to send a portion of our specimens to both the pathologist and the physiologist.[1] To our knowledge, at the start of this study, in 1952, oxygen quotient studies had never been reported on human liver.

As the Gillmans[2] and Waterlow and Patrick[3] have pointed out, in the study of altered metabolic regulation it is better to concentrate on dynamic processes rather than to measure metabolites of tissues. A study of tissue enzyme activity would appear to help us to get nearer to a basic understanding of the problem. In 1954, Waterlow and Patrick[3] reported their progress with enzyme studies on fatty liver in infants. Various enzyme systems were investigated in their series, and there was a suggested reduction in cholinesterase and succinoxidase activity in fatty liver tissue.

Method

The 10 patients used in this study were undergoing surgery for gallbladder, colon, or pancreatic disease or peptic ulcer; 4 patients with obstructive jaundice had liver-function studies in the course of their preoperative evaluation. Wedge biopsy specimens weighing approximately 1.5 gm. were removed from the liver edge in 10 patients and placed into a precooled sterile container. The specimen was then immediately sectioned, weighed, and placed in the Warburg apparatus for oxygen determinations. The oxygen consumption was determined by the direct Warburg procedure on slices, with Krebs-Ringers succinate as the substrate.[4] Oxygen consumption was expressed as QO_2, or the number of microliters of oxygen consumed in one hour by 1 mg. (dry weight) of tissue. Biopsy specimens were taken early in the operative procedure to avoid a factor of prolonged anesthesia and shock. Both general and spinal anesthesia were used. Concomitant liver sections for histological study also were made for most of these individuals.



Liver succinoxidase QO_2 and serum bilirubin levels in four patients with obstructive jaundice.

Results

There was no increased morbidity referable to the liver biopsy performed at the time of laparotomy. The six patients with grossly normal livers underwent subtotal gastrectomy in five instances, and one had a resection of the transverse colon. The histological examination of liver biopsy specimens, available in four of these patients, suggested no functional liver pathology. The oxygen consumption, expressed as QO_2, varied from 4.74 to 8.86 in these six cases (average 6).

Three patients in this series underwent palliative surgery for malignancy at the head of the pancreas; another patient had common-duct stones with obstructive jaundice. Each patient showed hepatic derangement, both by histological examination of the liver and by the liver-function studies. Their QO_2 determinations varied from 3.63 to 6.79 (average 5.3). The patients with the highest bilirubin levels had the lowest QO_2 values (see the table and the figure). How-

---

From the Department of Surgery, University of Miami School of Medicine and United States Veterans Administration Hospital, Coral Gables, Fla.

ever, surgery was frequently performed considerably after the bilirubin determination had been done, and, therefore, all bilirubin values could have been higher at laparotomy. The patient with the most severe liver damage died on the ninth postoperative day in hepatic and adrenal failure.

Comment

The presence of succinic dehydrogenase in tissues was discovered by Battelli and Stern,[5] who noted that, when succinate was added to certain tissues, the oxygen uptake was markedly increased and malic acid was produced. More recent work has shown that the catalytic dehydrogenation of succinate is the result of the action of succinic dehydrogenase, cytochrome-C, and cytochrome oxidase.[6] The components of this reaction are referred to as the "succinoxidase system." Succinic dehydrogenase is found in bacteria, molds, insects, and most tissues of vertebrates that have been tested. Schneider and Potter [6] determined the activity in heart, kidney, liver, brain, skeletal muscle, spleen, lung, and Jensen sarcoma of the rat.

Findings in Ten Surgical Patients on Whom Respiratory Liver Metabolism Studies Were Done

Date	Diagnosis and Operation	Type of Anesthesia Before Liver Biopsy	Finding on Microscopic Examination of Liver Biopsy Specimen	Liver-Function Tests	QO_2
1/14/53	Peptic ulcer (duodenal); gastric resection	Continuous spinal, intravenous; 10 mg. tetracaine (Pontocaine) hydrochloride, 1/150 grain (0.4 mg.) scopolamine	No examination	None	4.78
1/21/53	Cancer of transverse colon, gastric polyp; resection	Continuous spinal, intravenous; 5 mg. tetracaine, 50 mg. meperidine, 1/300 grain (0.2 mg.) scopolamine	No examination	None	4.86
1/28/53	Obstructive jaundice, cancer of head of pancreas	Intravenous, inhalation; 0.25 gm. thiopental (Pentothal) sodium, cyclopropane	Obstructive jaundice	12/31/52: icteric index 93 units; cephalin flocculation 2+; alkaline phosphatase 25 Bodansky units, thymol turbidity 2.8 units/100 cc.; serum bilirubin 13 mg (van den Bergh direct 6.6, indirect 6.4), cholesterol 1,087 mg., cholesterol esters 80 mg./100 cc.	6.17
2/6/53	Duodenal ulcer; gastric resection	Intravenous, inhalation; 0.5 gm. thiopental, 60 units curare	Hemosiderosis	None	6.03
2/9/53	Common-duct stone; common-duct exploration	Spinal, intravenous; 10 mg. tetracaine, 50 mg. meperidine	Hemosiderosis; obstructive jaundice	1/28/53: sulfobromophthalein retention 47.5% after 45 min.; icteric index 28.9; cephalin flocculation 4+; alkaline phosphatase 20 Bodansky units, thymol turbidity 2.2 units/100 cc.; serum bilirubin 3.55 mg. (van den Bergh direct 2.5, indirect 1.05), cholesterol 268 mg./100 cc.	6.79
2/10/53	Marginal ulcer; gastric resection	Intravenous, inhalation; 0.5 gm. thiopental, 60 units curare, cyclopropane	Hemosiderosis	No liver-function studies; total serum proteins 7.8 gm., with 4.29 gm. albumin and 3.51 gm. globulin/100 cc.	4.74
2/12/53	Obstructive jaundice, cancer of pancreas	Continuous spinal; 4 mg. tetracaine	Obstructive jaundice	2/11/53: Urine 4+ for bile, negative for urobiligen; icteric index 122; cephalin flocculation 4+; alkaline phosphatase 53 Bodansky units, thymol turbidity 2.2 units/100 cc.; total serum proteins 6.6 gm., with 8.5 gm. albumin and 3.1 gm. globulin/100 cc.; serum bilirubin 27.7 mg. (van den Bergh direct 16 mg.), cholesterol esters 64 mg./100 cc.	3.63
2/16/53	Chronic duodenal ulcer; gastric resection	Continuous spinal; 6 mg. tetracaine	Hemosiderosis	None	6.45
2/18/53	Peptic ulcer; gastric resection	Continuous spinal, intravenous; 10 mg. tetracaine, 100 mg. meperidine, 1/150 grain scopolamine	Hemosiderosis	None	8 86
3/16/53	Cancer of head of pancreas	Intravenous, inhalation; 0.5 gm. thiopental, cyclopropane	Obstructive jaundice	3/2/53: icteric index 112; cephalin flocculation 1+; alkaline phosphatase 14.7 Bodansky units, thymol turbidity, 1.3 units/100 cc.; serum bilirubin 20.8 mg. (van den Bergh direct 14.3, indirect 6.5) cholesterol 469 mg., cholesterol esters 135 mg./100 cc.	4.48

Several reports have appeared on the correlation of changes in activity of the succinic dehydrogenase of various tissues with changes in the function of these tissues. The activity in the rat embryo liver increases rapidly during the late embryonic and early postnatal life and reaches the adult level within 15 days after birth.[7] The activity is much lower in rat hepatoma than in normal liver, i.e., the activity in liver tumors is about one-fourth that in normal liver.[8] Meyer found that the activity in the functional corpus luteum of the ovary during pregnancy is two and one-half times greater than in the nonfunctional diestrous corpus luteum.[9] Studies of this type provide the basis for insight into the mechanisms of specialized physiological processes. The activity of succinic dehydrogenase in various kinds of tissues has been studied by determining the rate of reduction of methylene blue and by the measurement of oxygen uptake in the presence of the cytochrome system. By the use of the reaction mixture of Schneider and Potter for optimum activity,[6] the enzyme is made the limiting factor in the system and the oxygen uptake is a measure of the maximum activity of the dehydrogenase.

This pilot study was undertaken in an effort to determine whether direct physiological studies on human pathological tissues would be practical and informative. While voluminous reports are available on lower animals, this approach to the study of pathological physiology has been neglected in man. The succinic dehydrogenase enzyme system was selected because of the relatively high QO_2 readings that could be anticipated. The many other enzyme systems and methods of studying cellular activity provide numerous avenues for future research.

To date, oxygen-quotient studies do not appear to be practical from a clinical diagnostic standpoint. The limitations of in vitro studies are immediately apparent. It is not possible to state the normal QO_2

values for human liver from this small series. Normalcy, in the true sense, must be judged by normal liver-function tests and normal histological appearance. Samples from the liver edge may not be truly representative of the entire organ, although deep and superficial samples do not show any significant consistent changes in the cell count and appearance in our studies in dogs.[10] Waterlow and Patrick found the average oxygen-quotient value of succinoxidase in infants to be 4. Our QO_2 values were approximately 6 when averaged on six male adults. Another group with obstructive jaundice had slightly lower readings. This material is presented in the hope that it will stimulate interest in the possibilities of tissue physiology. Enzymatic investigations are now being extended to the study of experimental and clinical cirrhosis; the effect of anesthesia, anoxia, shock, and ischemia of the liver; and the effect of acute and chronic obstructive jaundice. Specimens from patients with acute and chronic hepatitis have not been available, for these patients rarely come to laparotomy.

Summary

Liver succinoxidase, oxygen-quotient, (QO_2) determinations were made on 10 patients undergoing upper abdominal surgery. Values suggested slight impairment of in vitro activity of the enzyme system in the presence of obstructive jaundice in comparison to apparently normal liver. The concept of performing direct physiological studies on human tissue is believed to be of possible value just as it has been in laboratory animals. The clinical physiologist could well fill some of the gaps in our understanding and assessment of problems of altered metabolism.

1242 duPont Bldg. (32) (Dr. Davis).

Virgil Moon, M.D., and Robert B. Thomson, M.D., reviewed the pathological material for this study.

DIRECT-VISION INTRACARDIAC SURGERY FOR PULMONARY STENOSIS

Earle B. Kay, M.D.
Henry A. Zimmerman, M.D.
and
Frederick S. Cross, M.D., Cleveland

In the past, cases of pulmonary stenosis have been surgically corrected by variations of the Brock[1] procedure, with instrumentation through the right ventricle to open the stenosed pulmonary valve. Swan[2] has demonstrated by postoperative cardiac catheterization studies that a valvulotomy so performed may be inadequate and responsible for failure of reduction of right ventricular pressure as compared to those performed by the open method through the pulmonary artery with the patient under hypothermia.

We have attempted to ensure an adequate valvulotomy by the use of direct-pressure measurements taken in the right ventricle and pulmonary artery at the operating table both before and after the valvulotomy in order to evaluate the effectiveness of the technical maneuver and adequacy of the opening.[3] If sufficient equalization of the two pressures on opposite sides of the pulmonary valve failed to occur, further attempts were made to open the pulmonary valve until the pressures approximated each other. By following this practice we were able to increase the number of satisfactory results, and in the presence of pure valvular pulmonary stenosis this appeared adequate.

It was not always possible, however, to determine the exact intracardiac lesions by the preoperative cardiac evaluation studies. In some instances, instead of a valvular stenosis an infundibular stenosis was found at the time of surgery in close proximity to the pulmonary valve; in others, we relieved a valvular stenosis only to find later that there was an additional infundibular stenosis present; and in still others a valvular stenosis was relieved only to be followed by the untoward pulmonary complications of an associated ventricular septal defect. Consequently, there are situations where direct visualization of the pulmonary outflow tract during surgery is not only desirable and advantageous but also mandatory.

There is no question that a stenosed pulmonary valve can be opened better under direct vision than by blind instrumentation. This is especially true in the treatment of infundibular stenosis, in which the closed techniques are even more unsatisfactory. With the use of heart-lung machine, oxygenation and sustained circulation can be maintained during open cardiotomy. This allows direct vision of the entire ventricular chamber valves, and septums. The congeni-

---

From the Surgical-Medical Service, St. Vincent Charity Hospital, and the Surgical Service, St. Luke's Hospital.

tally stenosed diaphragm representing the pulmonary valve can be retracted into the field of vision and opened, and new valve cusps can be fashioned. An associated infundibular stenosis can be easily excised. An associated ventricular septal defect, if present, is readily apparent and in turn can be adequately closed. Similarly, the atrial septum can be explored, and, if a defect of this septum is present, it too can be closed. Consequently, at the termination of the procedure a better operation has been performed; additional defects have been corrected, if present; and later complications such as pulmonary hypertension from an undetected ventricular septal defect have been avoided.

The operative findings present in the first five patients operated on with use of our heart-lung machine lend support to the above opinions (see table). Three of these patients had additional defects that had not been apparent preoperatively but that were easily detected and corrected under direct-vision surgery. The pump oxygenator employed during operation on these first five patients consisted of a rotating disk oxygenator in conjunction with a Sigmamotor pump. A Lauck pump is being substituted at the present time. The description of this machine and the experimental data will be the subject of a separate report.

Findings in First Five Patients Operated On

Case No.	Diagnosis, Preoperative	Found at Surgery
1	Valvular pulmonary stenosis	Valvular pulmonary stenosis
2	Valvular pulmonary stenosis Ventricular septal defect	Valvular pulmonary stenosis Ventricular septal defect
3	Valvular pulmonary stenosis	Infundibular pulmonary stenosis Ventricular septal defect
4	Valvular pulmonary stenosis	Valvular pulmonary stenosis Infundibular pulmonary stenosis Ventricular septal defect
5	Ventricular septal defect	High ventricular septal defect Low ventricular septal defect

The main argument against the employment of a direct-vision open cardiotomy is the possibility of a higher operative mortality, at least initially. We are in full agreement that extracorporeal circulation should not be employed until the operators are thoroughly versed not only with its experimental use but also with the technical problems associated with intracardiac surgery in patients. The machine in itself is only one of many factors that must be considered for success. There was one death among the first five patients, in the fourth one operated upon. This patient had severe cardiac malformations consisting of a valvular pulmonary stenosis, an extensive infundibular stenosis, and a large ventricular septal defect. It is felt that this death was not due to the use of the pump oxygenator with open cardiotomy per se but rather to the patient's severe underlying cardiac problem. He did well during the period of cardiac bypass perfusion but developed multiple cardiac standstills, necessitating massage after the thoracotomy incision was closed. The other four had their defects corrected and made an uneventful recovery.

Conclusions

The development of the pump oxygenator not only enables the cardiac surgeon to perform operations within the open heart under direct vision more effectively than heretofore possible with blind techniques but also permits him to detect and correct additional abnormalities that might otherwise remain undetected.

10465 Carnegie Ave. (Dr. Kay).

This study was supported in part by a grant from the Cleveland Area Heart Association.

ISOLATION OF JAPANESE B ENCEPHALITIS VIRUS

REPORT OF A FATAL CASE IN AN AMERICAN SOLDIER RETURNED FROM KOREA

Lieut. Col. Harold E. Shuey (MC), U.S. Army
and
Lieut. Col. Trygve O. Berge (MSC), U.S. Army

References to only three cases of Japanese B encephalitis occurring in persons in the United States after arrival or while en route to this country from epidemic centers in the Far East have been published.[1] From none of these was the isolation of the virus reported. To our knowledge, this is the first case of Japanese B encephalitis in the United States in which the etiological agent has been recovered.

Report of a Case

Present Illness.—A 22-year-old enlisted man was admitted to the U. S. Army Hospital, Fort Lawton, Wash., on Sept. 13, 1954, complaining of fever, retro-orbital pain, and headache of two days' duration, not relieved by acetylsalicylic acid, acetophenetidin, and caffeine (ACP) capsules or other medication. On the previous day, the patient had nausea and was hospitalized aboard ship after three episodes of vomiting. There were no cramps or diarrhea, nor was there any difficulty in urination.

History.—The patient had been with an ambulance company located at Chunkok, Korea, north of the 38th parallel, from Feb. 12 to Aug. 25, 1954. From Aug. 26 to Aug. 31, 1954, he was attached to a replacement depot at Pusan in southeastern Korea. On the latter date, he departed from Pusan for the United States on a military transport. Prior to the onset of the present illness, 11 days after boarding ship, he had been in perfect health. The patient denied any recent respiratory infection, cough, or sore throat. The history contained no mention of any insect bites.

Physical Examination.—On his admission to the hospital at Fort Lawton, the pulse rate was 118 per minute with regular rhythm. The temperature was 100.6 F (38.1 C) and the blood pressure, 138/70-62 mm. Hg. The ear, nose, and throat examination was

---

From the Sixth Army Area Medical Laboratory, Fort Baker, Calif.

negative. The chest was clear to auscultation and percussion. The heart was of normal size, and no murmurs were audible. The abdomen was scaphoid, and the liver and spleen were not palpable. There was no tenderness. All deep and superficial reflexes were equal and symmetrical. The admission diagnosis was idiopathic hemorrhagic fever.

Course in Hospital.—On the evening of Sept. 13, the temperature was noted to have ranged between 102 and 104 F (38.9 and 40 C) during the day. There was bilateral conjunctivitis and marked photophobia. The patient had become markedly confused. The pulse rate had fallen to 72 per minute. Respirations were 14 per minute, the temperature 102.4 F (39.1 C), and the blood pressure 140/70 mm. Hg. Nuchal rigidity and bilateral enlarged axillary lymph nodes were noted. The patient could move all extremities. The face was flushed. The attending physician felt that the diagnoses of choice were encephalitis or poliomyelitis. At 9 p.m. the patient complained of chills and continued retro-orbital headache. The temperature rose to 104.8 F (40.4 C). On Sept. 14 the temperature remained elevated, rising to 105.6 F (40.9 C). Mental processes slowed. The patient was unable to retain fluids. No petechiae were seen on the skin. The blood pressure was stable at 125/60 mm. Hg. Photophobia was marked. There were no changes in the nuchal rigidity or deep reflexes. The pupils were equal, but the fundi could not be examined because of the patient's inability to cooperate. At 3:20 a. m., Sept. 15, the patient was comatose and frothy sputum was seen in the mouth and nose. Wet rales were audible in the axillas. He was placed in a high Fowler's position, and tracheal suction and oxygen administration were instituted. The right pupil was dilated to 5 mm. Respirations were 24 per minute and labored. The blood pressure was 170/110 mm. Hg. The apical heartbeat gradually became weaker, and the patient died on the fourth day after the onset of illness. The final clinical diagnosis was acute encephalitis, possibly of Japanese B virus etiology, with terminal pulmonary edema.

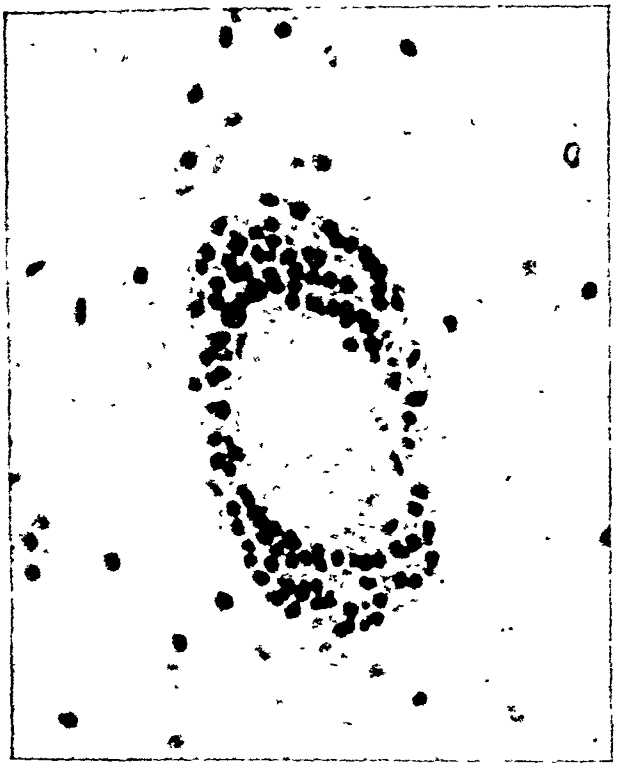

Fig. 1.—Photomicrograph showing perivascular cuffing with lymphocytes.

Laboratory Findings.—On Sept. 13 the hemoglobin level was 14.5 gm. per 100 cc. and the white blood cell count 15,500 per cubic millimeter, with 89% neutrophils, 6% lymphocytes, 4% monocytes, and 1% basophils. The urine had a specific gravity of 1.034, was amber in color, had an acid reaction, and contained a trace of albumin, amorphous urates, and sediment. A blood culture was negative. Roentgenograms of the chest were negative. On Sept. 14 the urine contained 20 to 25 white blood cells per high-power field. The spinal fluid contained 407 cells per cubic millimeter, with 29% polymorphonuclear leugocytes and 71% lymphocytes. The spinal fluid protein level was 57 mg. per 100 cc., with no increase in globulin. Another blood culture taken on this date was negative.

Gross Pathological Findings.—An autopsy performed nine hours after death revealed a well-developed male about 22 years of age weighing 185.5 lb. (84.1 kg.) and measuring 70 in. (177.8 cm.) in length. The external examination was not remarkable. The head and neck, thyroid, and mediastinum were within normal limits. The right lung weighed 840 gm. and the left, 720 gm. The cut surfaces revealed marked pulmonary edema and vascular congestion. The heart weighed 400 gm., and the valves and musculature were normal in appearance and measurements. The coronary arteries showed moderate atherosclerosis. The liver weighed 2,000 gm. and on cut section showed moderate edema. The gastric mucosa was moderately congested. The small intestine was minimally dilated without evidence of volvulus or paralytic ileus. The fecal matter in the large intestine was green and fluid in character. The spleen weighed 250 gm. and exhibited moderate congestion of the parenchyma. The pancreas was not remarkable. The combined weight of the adrenal glands was 14.9 gm. They showed minimal lipid depletion. The right kidney weighed 220 gm. and the left, 230 gm. The cut surfaces showed diffuse congestion. The genitourinary organs were otherwise normal in appearance. The brain weighed 1,520 gm. The convolutions were slightly flattened and the parenchyma mildly edematous. There was moderate congestion of the superficial vessels. No petechiae were noted in the gray or white matter. There was no obstruction in the ventricular system.

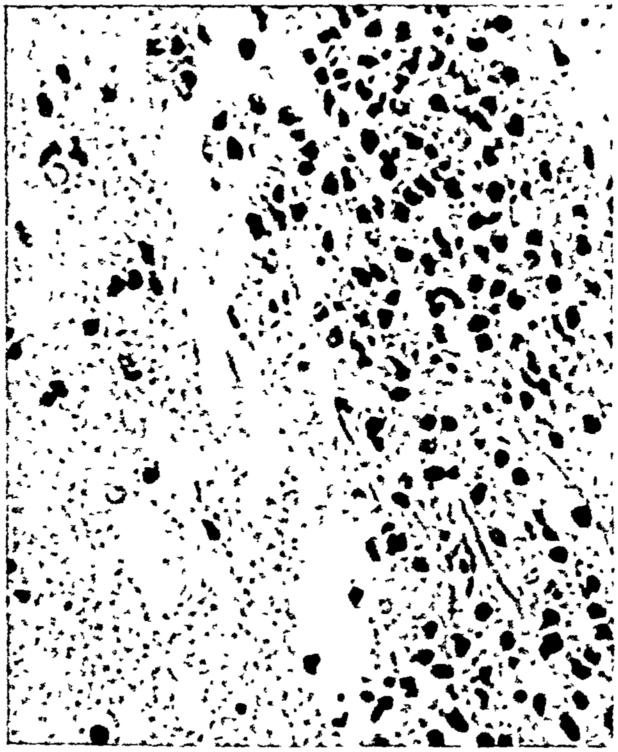

Fig. 2.—Photomicrograph showing microglial nodule and degenerating neurons (within and outside the lesion).

Microscopic Pathological Findings.—Sections of the lung revealed marked vascular congestion and protein-rich edema fluid within the alveoli containing numerous red blood cells and macrophages. The heart and aorta showed no significant findings. Liver sections showed marked congestion of the sinusoids, particularly around the central veins. The spleen sections revealed engorgement of the red pulp with blood. No significant findings were seen in the pancreas. Sections of the kidneys showed congestion of the glomeruli and of the blood vessels in the cortex and medulla and minimal cloudy swelling in the cells of the convoluted tubules. Multiple sections of the brain and spinal cord revealed widespread focal necrosis throughout the cortical gray matter and white matter, with infiltrations of lymphocytes and polymorphonuclear leukocytes. There was phagocytosis of ganglion cells, particularly prominent in the area of the olivary body. Satellitosis was noted in a few areas. There was diffuse cuffing of the blood vessels with round cells (fig. 1) but no perivascular hemorrhages within the parenchyma, although present in a few areas in the meninges. Small focal areas of necrosis were present in the cerebellum, but there was no dissolution of the Purkinje cells. In areas throughout the brain, a moderate glial proliferation was noted. Focal destruction of ganglions was seen in the basal nuclei. Within the spinal cord, areas of degeneration were noted with no singular localizing phenomena, although many were in the area of the anterior horn cells. There was some glial proliferation accompanied by infiltration with round cells and polymorphonuclear leukocytes (fig. 2). In general, the focal areas of necrosis were seen throughout the motor cortex, basal ganglions, cerebellum, and spinal cord.

TABLE 1.—*Summary of Complement-Fixing Titers with Indicated Antigens Against Japanese B and St. Louis Encephalitis Guinea Pig Antiserums**

Antigens	Tested Serums: Titers JBE (Nakayama)	SLE (Hubbard)	Normal Serum
Isolated virus	1:128	1: 64	<1:32
JBE (Nakayama)	1:128	<1: 32	<1:32

Normal mouse-brain ..	<1: 32	<1: 32	<1:32

* Abbreviations: JBE, Japanese B encephalitis; SLE, St. Louis encephalitis

Isolation and Identification of Virus

Specimens of brain tissue and pectoralis major muscle were received in the frozen state for virus isolation attempts. Portions of spinal cord received in a separate container were found to have thawed en route. Portions of all tissues were ground in sterile 10% solution of skim milk, in a proportion of 10% by weight. After centrifugation to remove gross particulate matter, each suspension received 250 units of penicillin and 250 mg. of streptomycin per milliliter. Bacteriological cultures of the suspensions in thioglycollate broth showed no evidence of viable organisms. Groups of newborn white mice (1 to 3 days of age) were inoculated with 0.01 ml. intracerebrally and 0.03 ml. intraperitoneally of the respective tissue emulsions. Young weaned mice (21 days) received 0.03 ml. intracerebrally. In addition, 6-day-old chick embryos were inoculated with 0.1 ml. amounts of the various suspensions by the stab method.

No agent was recovered either from the muscle tissue or from the spinal cord material in mice or in embryonated eggs in the original passage attempts. Blind passages were not made. Five of eight newborn mice inoculated with cerebral tissue, however, showed signs of illness on the fourth postinoculation day and were killed for passage. The remaining mice were moribund on the sixth and seventh days. Adult mice inoculated with the same material showed signs of illness first on the sixth day, followed by definite paralysis and death on the eighth and ninth days. A single mouse survived the first passage observation period of 28 days. Cultures of brain material from killed mice were bacteriologically sterile. The same human brain emulsion inoculated into six-day embryonated eggs produced death of the embryos on the fourth to the sixth day. This line was not continued, since the agent appeared to produce disease readily in mice.

The agent was established in second mouse-brain passage by inoculation of 10% solution of infected brain suspension intracerebrally from suckling mice into new groups of newborn and young adult mice. All of 28 newborn mice showed spasms on the third day after inoculation and were killed for seed virus and antigen preparation. Young adult mice showed ruffled fur and a hunched position on the third day, at which time one-half of the mice were killed. The remaining mice died on the fourth and fifth days.

Antigen for virus identification by the complement-fixation technique was prepared from infected mouse brains harvested three days after inoculation. Brains were ground in sterile saline solution to a concentration of 20% by weight and stored overnight at 5 C. The emulsion was then centrifuged at 2,000 rpm for 30 minutes; the supernatant fluid was drawn off and again centrifuged in the cold for 30 minutes at 10,000 rpm. Aqueous merthiolate was added to the high-speed supernatant to a final concentration of 1 in 10,000 as a preservative, and the supernatant was employed as a complement-fixing antigen in box titrations against Japanese B encephalitis (JBE) and St. Louis encephalitis (SLE) guinea pig immune serums. The results are summarized in table 1. Results, while suggestive, were inconclusive, because of the marked cross reaction with both JBE and SLE antiserums.

TABLE 2.—*Identification of Isolated Virus as Japanese B by Intracerebral Neutralization Tests with Known Guinea Pig Immune Serums*

Tested Serums	Dilutions of Virus 10^{-5}	10^{-6}	10^{-7}	10^{-8}	10^{-9}	LD_{50}	Logs Neutralized
Normal rabbit	6/6*	6/6	4/6	2/6	0/6	$10^{-7.6}$	—
JBE (Nakayama)	2/6	1/6	0/6	—	—	$10^{-4.9}$ or <	2.6 or >
SLE (Hubbard)	6/6	6/6	3/6	0/6	—	$10^{-7.0}$	0.5
WEE (Rockefeller Institute)	6/6	6/6	3/6	1/6	—	$10^{-7.2}$	0.3

* *Numerator indicates* number of deaths; denominator indicates number of mice inoculated.

Identification of the virus was made by means of the intracerebral mouse neutralization test,[2] with use of mouse-brain virus and known guinea pig antiserums. Undiluted antiserums for JBE, SLE, and Western equine encephalomyelitis (WEE) viruses were tested in tenfold dilutions of the unidentified second-passage mouse-brain virus. As shown in table 2, JBE antiserum was found to neutralize at least 2.6 logs of virus, while SLE and WEE antiserums neutralized 0.5 log or less.

A portion of the original human brain material was transmitted to the Department of Virus and Rickettsial Diseases, Walter Reed Army Institute of Research, for confirmation of the isolation and identification. The report indicated that an agent that caused fatal nervous system disease in suckling and adult mice was again recovered. The agent was shown to produce viremia in newly hatched chicks, and chicks thus infected were found, two weeks after infection, to possess hemagglutination-inhibiting antibody for JBE virus, by use of the technique developed at the 406th Medical General Laboratory.[3] Serums obtained from infected chicks six weeks after inoculation were also shown to neutralize nearly 4 logs (10,000 L. D_{50}) of a known strain of JBE virus by the conventional neutralization test in mice (table 3).

Comment

Outbreaks of Japanese B encephalitis have been described by Sabin and co-workers[4] and by Lincoln and Sivertson[5] among American military personnel stationed in epidemic areas in the Far East, including Korea. The latter authors detailed their findings in more than 200 cases occurring in soldiers in the Pusan perimeter in the late summer and fall of 1950, the area where the present patient most likely contracted the infection in 1954. A probable incubation period of 8 to 15 days has been ascribed to this disease[6]; the patient was in Pusan between the 11th and 17th days prior to the onset of illness.

[*] Data furnished by Department of Virus and Rickettsial Diseases, Walter Reed Army Institute of Research

† EEE, eastern equine encephalitis

Although no attempt was made to recover the virus from the blood of the patient reported here, it is quite possible that he had viremia when he arrived in the United States. Renewed emphasis should be given to the warnings of Hammon[7] and Reeves[8] of the possibility of introduction, by cases such as this, of the Japanese B encephalitis virus into the United States where potential vectors and suitable hosts are present. Reeves and Hammon[9] have demonstrated that seven species of three genera (Culex, Aedes, Culiseta) of mosquitoes indigenous to the western U. S. can transmit a mouse-brain-adapted strain of JBE virus to mice in the laboratory. These authors consider that the virus might well become established if introduced into areas where our native encephalitides are now endemic.

Summary

A fatal case of Japanese B encephalitis developed in an American soldier returning from Korea. Etiology of the disease was established by recovery of the virus from brain tissue and its identification by neutralization tests with specific immune serums.

Lieut. Col. William C. Butz, M. C., U. S. Army, Chief of Laboratory, Madigan Army Hospital, furnished the clinical abstract and autopsy findings.

Carmen Morris and Beatrice England gave technical assistance in this study.

Duodenostomy.—Duodenostomy has not been accepted as a standardized procedure. Undoubtedly misfortunes have followed its use in some cases. . . . Possibly the untoward sequelae were the result of faulty technique in the performance of gastric resection rather than imperfection in the procedure per se. In the past seven years, our opinion has been strengthened that the occasional selected utilization of duodenostomy will provide a margin of safety that cannot otherwise be achieved. . . . A controlled duodenal fistula is preferable to an insecurely closed duodenal stump which may result in leakage. Welch has advocated the use of concomitant catheter jejunostomy. We consider this to be an unnecessary adjunct. Possibly our enthusiasm to study the procedure may have stimulated us to utilize duodenostomy more frequently than was absolutely necessary. On the other hand, the procedure could have been employed advantageously in a few other selected cases. In our hands we have found duodenostomy preferable to an insecure closure of the duodenal stump by other methods. Its greatest field of usefulness may lie in the hands of younger less experienced gastric surgeons. As our experience with duodenostomy has increased, we have become more enthusiastic about the advantages of its occasional selected use and less impressed with its disadvantages. The two most serious complications, leakage about the catheter and electrolyte imbalance due to the loss of duodenal content, have in our hands been of no consequence. Proper closure of the duodenum about the catheter plus the use of Penrose drains has rendered the first complication inconsequential. Proper performance of gastric resection renders obstruction in the afferent loop almost nonexistent. The development of a persistent duodenocutaneous fistula . . . did not occur in our series.—C. G. McEachern, M.D., R. E. Sullivan, M.D., and J. E. Amis, M.D., Duodenostomy, A. M. A. Archives of Surgery, June, 1956.

FRANK BILLINGS MEMORIAL LECTURE

William S. Middleton, M.D., Washington, D. C.

Appropriately, we are met today to honor the memory of a great clinician and medical statesman, Frank Billings, in Chicago, where his fine professional stature and eminence were attained. In 1878, a sturdy farm lad from Iowa County, Wisconsin, matriculated in the Chicago Medical College (now Northwestern University Medical School). Of splendid Anglo-Saxon stock, he was superbly endowed physically and intellectually. Upon completion of a common public school education, young Billings had attended the Platteville (Wisconsin) State Normal School for two years. Thereafter, he taught a country school in the town of Eden. His prompt advancement to the principalship of the Platteville High School was, in retrospect, a true forecast of his driving ambition and capacity.

Upon graduation from the Chicago Medical College, Dr. Billings served an internship in Cook County Hospital, a coveted post for the young physicians of that period. The investment of postgraduate studies in London, Paris, and Vienna gave his career an impetus that brought him shortly to the forefront of medicine in Chicago. Aside from Dr. Billings' personal attributes, his activities in the introduction of laboratory methods into clinical practice were probably the "open-sesame" to his initial success that eventually carried him to a position of preeminence in American medicine.

Dr. Billings was a born leader. He literally dominated every gathering he attended by the force of his presence and personality. Both at Northwestern University Medical School and at Rush Medical College, his efforts brought fruit in the improvement and the expansion of the physical plants. He was particularly effective in enlisting the financial support of wealthy Chicagoans in medical philanthropy. From his vantage point, Dr. Billings led the attack on nostrums and subnormal medical schools. The Council on Pharmacy and Chemistry and the Council on Medical Education and Hospitals of the American Medical Association were natural products of his energetic representations. His thoughts on medical education were especially advanced in the advocacy of the utilization of full and part-time clinical teachers in an integrated program. His recommendations for the coordination of public and private hospitals in a teaching plan are still valid and might be reviewed with profit in the light of a changing picture. With characteristic prescience, Dr. Billings urged the establishment of a national examining board.

Lest the erroneous impression of an impersonal austerity be gathered from this recital of achievements, it should be recorded that Dr. Frank Billings was fundamentally a warm, kindly man. Physically massive, he was just as large of heart. Out of the abundance of his life and substance he gave unstintingly to every worthy cause. The connotation of the term "builder" that is so regularly applied to Dr. Billings in this community may deprive posterity of a measure of the deep humanity of the man. Rarely are the dominant qualities of accepted leadership so blended with the depth of human sympathy that characterized him. His students, nurses, interns, and associates adored him. Dr. Billings died in his 79th year (Sept. 20, 1932). His memory is held in reverence by a host of friends, both lay and professional, who were privileged to associate with him in his manifold activities.

Development of the Study of Disease

Health is no longer viewed in the negative sense as the mere absence of disease. Health connotes a harmony of mind and body with self and environment. This balance will obtain with the normal activity of every vital and supporting function. The nice adjustments of the body to its surroundings have been grouped under the term homeostasis by Cannon. Selye has extended this concept in his theory of adaptation. The internal milieu of the mammalian body is a complex, ever-changing medium of physical, physiological, and chemical factors so integrated in health as to maintain a sense and a presence of well-being. The present viewpoint, for example, emphasizes the continuous alterations in chemical constituents upon momentary changes in bodily or tissue requirements. Such changes may involve simple chemical reactions, or they may invoke complex physical, enzymatic, and steroid mechanisms. As long as the reserve of the involved elements is adequate, physiological equilibrium may be maintained. To this harmonious balance, the term eucrasia (eucrasy) has been applied.[1] An unnatural imbalance through an exhaustion of the reserves or an inability to meet demands from normal or abnormal sources results in a disturbance of function. Such disruptions find expression in symptoms and eventually in signs arising from pathological changes in tissues or organs.

From the beginning of recorded time, man has endeavored to interpret the manifestations of disordered function. The concepts reflect the state of human knowledge of a given period. From time to time, medical advance has been impeded by attempts to apply rigid criteria in the grouping of diseases. Nosology has, on occasions, been viewed as an end rather than an instrument in our hands. Indeed, systems of practice have been built on such insecure foundations. With the ascendancy of morbid anatomy and the splendid dividends from clinical-pathological correlations in the early 19th century, "dead-house" medicine dominated the scene for a period. In fact, in certain quarters no diagnosis was complete without the autopsy findings! Microbiology came into high estate in the late 19th and early 20th centuries. With its rise came the clinical fixation upon etiology. The last three

Read before the Section on Internal Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

decades have witnessed an upward surge in the physiological and the physiological-chemical knowledge of bodily reactions in health and disease. The impact of physical, physiological, steroid, enzyme, and nuclear physical-chemical observations on medical thought and practice has been stupendous in recent years and will increase.

In this advance, medicine must never lose sight of fundamental facts. Sydenham[2] wrote, "A disease in my opinion, how prejudicial soever its cause may be to the body, is *no more than a vigorous effort of nature* to throw off the morbific matter, and thus recover the patient." In this light, disease must not be considered as an isolated phenomenon nor a series of more or less related phenomena. Man is rarely the passive host of "morbific matter" but reacts more or less violently, dependent upon the nature of the alteration induced locally or generally. Regardless of whether the inciting factor be microbial, nutritional, metabolic, degenerative, or neoplastic, there are always contributing circumstances in the evolution of the state of inequilibrium termed disease that must be given due consideration in the true comprehension of its natural history.

Within the memory of many physicians still active in the practice of medicine, there have been many radical changes in the mode of infectious diseases and in the clinical expression of specific infections. The exanthems are waning in incidence and severity. Black measles, black scarlet fever, and black smallpox are now only terrifying memories. Diphtheria, with its toll of morbidity and mortality, is largely controlled. Typhoid no longer recurs each summer and autumn to reflect the limitations of sanitation and the contamination of the water (and milk) supply. Lobar pneumonia is a rarity in our teaching hospitals. Suppurative mastoiditis and empyema are relics of a past that medicine would forget. Tuberculosis is losing some of its terror, but it is by no means a vanquished threat to health and life. Syphilis and gonorrhea are more adequately treated than ever before, but the failure to eradicate these diseases reflects the limitations of purely curative medicine. Moreover, man is paying a penalty for the disruption of the biological balance of nature through the introduction of antimicrobial agents. Resistant strains of pathogenic bacteria are appearing. Rickettsial and viral infections have increased with the abatement of bacterial diseases. With the change in the flora of the body under antimicrobial therapy, fungal infections have emerged in increasing frequence.

Observation and Experimentation

The time for reflection is now at hand. Before the countenance of certain of these diseases has vanished from the earth, we must attempt to commit to the printed record every detail of their course. At best, our observations are fragmentary. The published accounts of diseases too frequently represent the subjective reports of the patient, supplemented by the periodic examinations of the physician. From these bits and pieces, a composite picture is reconstructed. This reproduction is frequently at variance with the autobiographic accounts of physicians suffering from the same disorder. Sydenham's[2] account of his own gouty attacks is a classic example of this truth. A physician should be a "minister (or servant) and interpreter of nature" (Hippocrates). By observation and experimentation, medicine must strive to fill the gaps in a comprehensive understanding of the natural history of disease.

Sir Thomas Lewis,[3] while deploring the cleavage, bespoke the separate training of physicians for clinical medicine and for clinical science: "This science seeks, by observation and otherwise, to define diseases as these occur in man: it attempts to understand these diseases and their many manifestations and, here especially, makes frequent use of the experimental method." In his evolution of the thesis, Lewis indicated that two different types of psychological attributes were involved: "Self-confidence is, by general consent, one of the essentials to the practice of medicine, for it breeds confidence, faith and hope. Diffidence, by equally general consent, is an essential quality in investigation, for it breeds inquiry." Obviously, an acceptance of this position would spell a sharp limitation to the observational approach of which Lewis stated, "Eventually, however, the fertility of this method greatly declines by a process of exhaustion and, for those who can read the signs, this time has come in medicine." Trotter[4] voiced a similar reservation thus: "This limitation is the circumstance that the observer must wait upon the natural occurrence of the phenomena he wishes to study. The phenomena may be too infrequent for their significant recurrence to come within the span of human life, they may be too complex and too closely mixed with irrelevant events for the invariable sequence they possess to be detected."

Actually, the contention that observational and experimental skills are incompatible is untenable. The ramifications of the scientific approaches to the study of man in health and disease exceed the capacity of any physician to encompass, much less to apply them to the multitudinous clinical problems with which he is confronted. Wherever possible, these scientific methods must be invoked in the elucidation of covert situations, but a proper sense of proportions must be preserved. Mackenzie[5] said, "When I see the modern cardiologist getting his assistant to take an x-ray photograph of the heart and electrocardiogram, and even a blood-pressure reading, and then behold him sitting down to study these reports, I am truly amazed. I never could have realized that the practice of medicine could have become so futile and ineffective." Certain of the random chemical probings in the guise of medical practice are even more astounding. Without depreciating these studies one iota, let it be clearly understood that the only individual competent to direct the care of the patient is the physician. If he be wise, he will welcome the support of his associates in the basic sciences for coordinate clinical study. From their joint efforts will come a more complete understanding of the patient's problems and more intelligent treatment.

Indeed, out of such cooperative efforts have come material advances in the clinical appreciation of certain disorders in very recent years. Pheochromocytoma was a poorly understood neoplasm until physiologists and pharmacologists clarified the background. Aldosteronism emerged as a distinct clinical entity upon the definition of its steroid responsibility. Agammaglobulinemia awaited electrophoretic fractionation of the serum protein for elucidation of the attendant recurring infections. The unusual symptoms and signs attendant upon carcinoid of the intestinal tract with hepatic metastasis represent an extraordinary example of the interdependence of observation and experimentation in the explanation of disordered function. With Charcot we may say, "Disease is from of old and nothing about it has changed. It is we who change, as we learn to recognize what was formerly imperceptible."

Hence, it behooves the physician to preserve his clinical acumen, as he accepts and extends the application of newer laboratory methods to the study of his patients. Indeed, his position must be fortified from a psychological standpoint to avoid the impersonality of the laboratory. If the physician is to capitalize on this advantage, however, the time is ripe for a new approach to the natural history of disease. With due attention to the experimental and laboratory contribution to this vital subject, there remains a vast area for reexploration and inquiry. John Brown[4] wrote, "Symptoms are universally available; they are the voices of nature." Mackenzie[5] said, "When we search for the recondite and the obscure, we fail to recognize the simple and the obvious." The English school has produced a number of great clinicians in the Hippocratic pattern. Thomas Sydenham[6] said:

> In writing, therefore, a history of diseases, every philosophical hypothesis which hath prepossessed the writer in its favor, ought to be laid aside, and then the manifest and natural phenomena of diseases, however minute, must be noted with utmost accuracy, imitating in this the great exactness of painters, who in their pictures copy the smallest spots or moles in the originals; for it is difficult to give a detail of the numerous errors that spring from hypothesis.

Thomas Willis[7] was a true seeker for knowledge, as witnessed in the following statement:

> After I had not found in Books what might satisfy a mind desirous of truth, I resolved with myself to reach into living and breathing examples; and therefore sitting oftentimes by the Sick, I was wont carefully to search out their cases, to weigh all the symptoms and to put them, with exact Diaries of the Diseases, into writing, then diligently to meditate on these; and then begin to adapt general notions from particular events.

In a similar spirit, William Heberden[8] afforded the following plan:

> The notes, from which the following observations were collected, were taken in the chambers of the sick from themselves, or from their attendants, where several things might occasion the omission of some material circumstances. These notes were read over every month and such facts as tended to throw any light upon the history of a distemper or the effects of a remedy, were entered under the title of the distemper in another book, from which were extracted all the particulars here given relating to the nature and cure of diseases.

Heberden's account of diabetes[8] serves as an example of the application of his method:

> An unusual thirst is first taken notice of, with a tongue rough and furred, and a bad taste in the mouth; the appetite fails; the pulse is too quick; the strength and flesh waste; the skin is in a burning heat, without the least tendency to sweat; the thirst makes these patients drink immoderately, and of course they make water much more frequently than is common to them, and in much larger quantities, like hysterical persons. . . . The urine in a diabetic is said to have a honey-like sweetness; but, in my judgment, formed upon the most perfect cases of this distemper, it ought in most persons rather to be called insipid; in one joined with a fever, I found it sweetish.

Even more illustrative of Heberden's clinical portraiture is the account of angina pectoris first published in 1768.[8] Indeed, this account may be taken as a proper model for the natural history of disease. Abstracted in essential detail, it reads:

> The seat of it, and sense of strangling and anxiety with which it is attended, may make it not improperly be called angina pectoris.
>
> They who are afflicted with it, are seized while they are walking (more especially if it be up hill, and soon after eating) with a painful and most disagreeable sensation in the breast, which seems as if it would extinguish life, if it were to increase or continue; but the moment they stand still, all this uneasiness vanishes.
>
> In all other respects, the patients are, at the beginning of this disorder, perfectly well, and in particular have no shortness of breath, from which it is totally different. The pain is sometimes situated in the upper part, sometimes in the middle, sometimes at the bottom of the os sterni, and often more inclined to the left than to the right side. It likewise very frequently extends from the breast to the middle of the left arm. The pulse is . . . not disturbed by this pain. . . . Males are most liable to that disease, especially such as have passed their fiftieth year.
>
> After it has continued a year or more, it will not cease so instantaneously upon standing still; and it will come on not only when the persons are walking but when they are lying down, especially if they lie on their left side, and oblige them to rise up out of their beds. In some inveterate cases it has been brought on by the motion of a horse, or a carriage, and even by swallowing, coughing, going to stool, or speaking, or any disturbance of mind. . . .
>
> Some have been seized while they were standing still or sitting; also upon first waking out of sleep; and the pain sometimes reaches to the right arm, as well as the left, and even down to the hands, but this is uncommon: in a very few instances the arm has at the same time been numbed and swelled. . . .
>
> The termination of the angina pectoris is remarkable. For, if no accidents intervene, but the disease go on to its height, the patients all suddenly fall down, and perish almost immediately. Of which indeed their frequent faintnesses, and sensations as if all the powers of life were failing, afford no obscure intimation.

Infectious Diseases

Unfortunately such accuracy of clinical observation is the rare exception in modern medical writings. This deficiency becomes increasingly apparent in the welter of laboratory data, relevant and irrelevant, that so frequently clutters papers in the medical journals. The natural history of the infectious diseases has been reasonably well recorded. Particularly is this true where the etiological agent has been isolated. Contributing to the adequacy of the natural history of the acute infections has been their clear-cut definition and their self-limiting course in many instances. The knowledge of exposure and the routes and portals of entry of the etiological agents has been quite comprehensive. The ability to establish incubation periods, prodromes, symptoms and signs of the fastigium, and the manner of defervescence to convalescence for the acute infectious diseases has lent great impetus to this effort. In most instances, the laboratory has afforded material support to the completion of the individual picture. Great hiatuses still exist in the knowledge of susceptibility and immunity. Actually, the advent of the antimicrobial agents, while a great beneficence to humanity, has delayed the attack on some unsolved problems in this area. In the first place, the opportunity to study the natural history of a given bacterial infection is limited by the almost universal administration of antimicrobial agents at the earliest moment. Not infrequently, the broad-spectrum antimicrobial agents have been given on suspicion before the etiology has been established. The vis medicatrix naturae is overlooked in the medical thought of many contemporary physicians. Certainly, Gairdner's admonition[9] is completely outmoded in modern medicine: "There is one stipulation that I must make with those who desire to follow out this inquiry with the view of testing the normal mode of the crisis in typhus fever. It is, that *as many cases as possible should be left to their normal course, unaffected by either drugs or stimulants.*" Assuredly, the effectiveness of the antimicrobial agents in the treatment of lobar pneumonia, typhoid, and a host of other bacterial diseases seriously delimits any prospect of extending the knowledge of their natural history. A further deterrent to advances in this area has been the shifting emphasis in interest and study. This circumstance is doubly unfortunate in the unexplored fringes of this broad field.

Constitutional Disorders

The case of the constitutional disorders is much more involved. Many of the factors formerly attributed to heredity are now viewed as environmental and even infectious in origin. The area is wide open for a frontal attack. The degenerative and neoplastic diseases afford a fallow field for this approach. Mackenzie forsook a lucrative practice and an assured future in Harley Street to pursue this angle in St. Andrews, Scotland. He had two objects: "(1) understanding of the mechanism of symptoms, and (2) understanding of their prognostic significance."[5] In his biographer's phrase he urged his contemporaries "to forsake the study of death for that of life."[10] The way is not easy, but the future growth of clinical medicine is inextricably bound with a refinement and a discriminating use of the proved methods of clinical observation. The pathogenesis of atherosclerosis, for example, will be more clearly understood when all contributing factors in its initiation are brought into focus and their relative importance fixed. The familial occurrence of vascular degeneration is a commonplace observation, yet heredity has been discredited in some studies and dietary factors have been given increasing responsibility. The exact part of faulty cholesterol metabolism in the ultimate atherosclerotic process is still uncertain. The pendulum is apparently swinging toward a secondary relationship. In developing the natural history of this degenerative disorder, increasing attention must be devoted to the detailed history, with especial reference to the occurrence and the complications of past illnesses, social history, including habits and exposures, family history, and the evolution of the referable complaints. Since physicians have a conspicuous predisposition to atherosclerosis, they might render a conspicuous service by affording clinical autobiographies in this direction. Added to this approach would be the invaluable laboratory studies that anticipate and measure gross changes in pathological physiology. Billings[11] wrote, "Medicine today is applied science. If we utilize the knowledge of today in an attempt to cure and prevent disease, it must also be an experimental science. . . . Experimental medicine must be the means of removing the ignorance which still embraces so many of the maladies which afflict manhood."

Neoplasia arises from so many causes as to render a generic factor difficult of definition. Yet there may prove to be a single basic etiology with a number of variants responsible for the development of specific new growths. Painstaking studies of patients with neoplasms may add materially to our knowledge of their inception and course. Furthermore, especial attention to departures from the rule in apparent susceptibility and resistance to given tumors in certain strains may afford leading clues to the fundamental origin of neoplasia. While great progress has been made in this direction, the clinician is woefully deficient in the tools for the early recognition of a majority of visceral tumors. Surface or accessible neoplasms will receive early and appropriate attention in most instances, but carcinoma of the pancreas, for example, has usually reached an inoperable stage when surgery is proposed. Deep-seated upper abdominal pain radiating to the back, painless progressive jaundice, sudden diabetes mellitus in individuals past 45 years of age, and unexplained phlebothrombosis are late manifestations of carcinoma of the pancreas. Yet they may be the first symptoms or signs that bring the patient to the physician. Frequently, cachexia has already become manifest. In a few patients, vague upper abdominal discomfort, coupled with marked introspection and nervousness, has anticipated frank symptoms and signs of carcinoma of the pancreas by months in our experience. In carcinomatous involvement of the head of the pancreas, melena, occult or overt, may be a guidepost. In such instances, roentgenologic confirmation may be anticipated. The chemical studies directed toward the quantitation of the digestive ferments of the external secretion of the pancreas afford little support to the early diagnosis of carcinoma. Here, then, lies one of the unsolved mysteries of medicine whose solution may be expedited by an "exact Diary of the Disease." Its parallels are innumerable.

If Hippocrates[12] be forgiven his sententious vein, the following quotation affords an excellent argument for a profound knowledge of the natural history of disease:

> And he will manage the cure best who has foreseen what is to happen from the present state of matters. For it is impossible to make all the sick well; and this, indeed, would have been better than to be able to foretell what is going to happen; but since men die, some even before calling the physician, from the violence of the disease, and some die immediately after calling him, having lived, perhaps, only a day or a little longer, and before the physician could bring his art to counteract the disease; it therefore becomes necessary to know the nature of such affections, how far they are above the power of the constitution; and, moreover, if there be anything divine in the diseases, and to learn a foreknowledge of this also. Thus a man will be the more esteemed to be a good physician, for he will be better able to treat those aright who can be saved, from having long anticipated everything; and by seeing and announcing beforehand those who will live and those who will die, he will thus escape censure.

Obviously, prognosis is a vital element in the practice of medicine. Its cultivation and acquisition are avidly pursued by all clinicians worthy of the name. Recently, Bloomfield[13] wrote a cogent editorial on the subject, in which he evaluated the factors in deriving such conclusions. With experience, he stated, "the analytical process may become lightning fast and indeed may be largely carried on subconsciously. The young doctor, however, may well profit by deliberately taking into account the various factors in prognosis . . . and by making a conscious analysis of the situation in case of his patients. Such a running of mental scales will help develop later virtuosity." With incisive insight, Ryle[14] remarked, "Prognostic ability is born largely of pathology and patiently gathered clinical experience. It evolves even more slowly than diagnostic ability. Minute and careful clinical observation, a good visual memory, and that necessary inquisitiveness about the subsequent course of cases which is nowadays systematized in the follow-up inquiry may all be numbered among the handmaidens of prognosis."

Conclusions

In a word, there is no royal road to success in the prognosis of human disease. Feeble though the reed may appear when tested by strict scientific standards, the patient or the family may properly expect general information as to the probable course of a given illness from the physician. Fortified by extended experience and careful study of the problems presented by the patient, the true natural historian, supported by discriminating laboratory studies, will become increasingly proficient and accurate in assembling the evidence for the diagnosis and prognosis. Furthermore, with a sound basic knowledge of the natural history of disease, he will not fall into the uncritical habit of therapeutic sophistry, but, with a broad perspective, his therapy will have direction and his conclusions of its effectiveness will reflect measured judgment.

"Sit down before fact as a little child, be prepared to give up every preconceived notion, follow humbly wherever and to whatsoever abysses nature leads, or you shall learn nothing" (Huxley).

This paper is being published simultaneously in the A. M. A. *Archives of Internal Medicine.*

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The Council has authorized publication of the following comments concerning "The Use of Chemical Additives in Food Processing," a report of the Food Protection Committee, Food and Nutrition Board of the National Research Council.

Eugene H. Stevenson, M. S.
Acting Secretary.

CHEMICAL ADDITIVES

Paul E. Johnson, Ph.D., Washington, D.C.

In an industrial, largely urban society such as that of the United States, it is necessary that food be provided for large numbers of people distantly removed from the site of production. The provision of an abundant, wholesome, and economical food supply requires that the foodstuffs be produced efficiently; be processed, preserved, and stored so as to minimize wastage and loss of nutritive value; and be distributed to the consumer in a sanitary condition. That the foods be diversified, esthetically appealing, and convenient to use is perhaps of only slightly less importance.

Many technological developments have been applied to the task of furnishing our food supply; important among them is the use of chemicals. There has been some public concern about the number and kinds of chemicals that enter the food supply during its production, processing, and storage. In 1950, this led to an investigation of the use of chemicals in foods by the Delaney committee of the U. S. House of Representatives. The report of this committee[1] stated that the U. S. Food and Drug Administration had estimated that 704 chemicals were used in foods. A list of the chemicals was not published, but the number cited included both the chemicals that are intentionally added to foods by the processor and those that may incidentally get into the food during its production, processing, and storage, such as insecticides, other pesticides, and detergents.

Recently the Food Protection Committee of the National Research Council undertook a study of the use of chemicals in foods for the purpose of evaluating the benefits arising from such use and appraising the significance of associated public health problems. One phase of this study involved a survey to determine the extent of use and the technological benefits of chemicals in food processing. A report of this survey is now available.[2]

The report is concerned only with intentional chemical additives—chemicals introduced into foods for the purpose of imparting some desired quality to, or of serving a functional purpose in, the foods. It describes briefly the technological reasons for using chemical ad-

ditives in the processing of each of six major classes of foods: cereal products, fruits and vegetables, beverages, dairy products, confections and other sweets, and meat products and fats. This is an informative account of the use of additives to facilitate processing and formulation, inhibit deterioration in storage, enhance and maintain nutritive value, and improve the appeal and acceptability of foods. These benefits to the consumer from the use of additives are so seldom recognized that a discussion of them deserves wide attention.

The major part of the report is devoted to a compilation of intentional chemical additives. In it are listed all the additives for use in meats and fats, those for which the committee was given authentic evidence of use, and those permitted by regulation in standardized foods. Approximately 550 additives, grouped according to function, are listed in the compilation. The foods in which the additives are used are given along with levels of use, whenever that information was available to the committee. The regulations concerning the additives promulgated by the Food and Drug Administration and the meat inspection branch of the U. S. Department of Agriculture are cited.

A small number of preservatives are used in processed foods. Familiar members of this group of additives are benzoic acid and sodium benzoate. The mold and rope inhibitors used in breads, sodium diacetate and the propionates, are also well known. Chlortetracycline, used on uncooked poultry to retard spoilage, and sorbic acid, a fungistat, are more recent additions to the list of preservatives.

Antioxidants, which are widely used in fats and in foods containing fats to retard oxidation and the resulting deterioration of flavor, include the sulfites and bisulfites as well as a group of organic chemicals. Among the latter are ascorbic acid and its salts, lecithin, and the tocopherols. Derivatives of hydroxytoluene, hydroquinone, and guaiaretic acid are also widely used. A few oxidizing additives, including chlorine, chlorine dioxide, peroxides, iodates, and bromates, are also employed, primarily as bleaching and maturing agents.

A wide variety and substantial number of additives are used to influence or stabilize the texture of processed foods. These act in many ways. In one group are the sequestrants, a class of salts that function by inhibiting the action of ions and that aid in emulsification through their effect on the proteins present in the food. A second group includes the surface active agents, among which are the monoglycerides and diglycerides and their derivatives and the polyoxyethylene and sorbitan esters of fatty acids. A third group consists of stabilizers and thickeners, which include the natural and synthetic gums, pectin, agar-agar and Irish moss derivatives, and alginic acid and its compounds.

A number of acids, alkalis, and buffers are used by food processors to adjust or stabilize the pH of their products. Many common organic and inorganic acids, bases, and salts are employed. Acids and bases have long been used in baking, in such a manner that their reaction will provide gas for leavening.

Two groups of chemicals are added to processed foods entirely or primarily for the purpose of increasing their esthetic appeal—the food colors and the flavoring agents. The food colors include both a number of natural dyes and the 16 FDC (food, drug, and cosmetic) certified colors. The flavoring agents form a large and diverse group, comprising some 300 essential oils, extracts, synthetic aromatic chemicals, and other materials. The greater part of the group are the synthetic flavors, which are employed very widely in many processed foods.

The nutrient supplements, vitamins and minerals, are classified as additives by the committee; the nonnutritive sweeteners, saccharin and the cyclamates, form a separate group. A final miscellaneous group contains additives of such diverse functions as candy polishes and glazes and yeast foods.

Safety of the additives for use in foods was not a matter of concern in the survey, and no discussion of safety is included in the report. The Food Protection Committee has previously stated that, as a basis for evaluating the safety of additives for use in foods, "information must be obtained on: (A) the chemical and physical properties of the additive . . .; (B) the biologic effects . . .; and (C) the anticipated levels and patterns of consumption."[3] The present report is the most complete source of information available for estimating levels of consumption of the additives. It contains quantitative data about usage of most, but by no means all, of the additives listed. Thus, an approximation of the quantity of an additive that might be ingested by a consumer with a given food habit can be formed.

There are limitations in the compilation for use in this way, however, which the committee points out. The list includes additives permitted by regulations but which may not actually be used. A particular additive may be used only seasonally or by only a part of the industry. Quantitative data given may represent the maximum rather than the actual or mean level of usage. Most of the classes of additives contain groups of alternative materials from which a selection may be made for use in a particular food product. These limitations do not detract from the value of the report as a reference; they do indicate caution in using it as a precise quantitative guide.

This report presents a realistic and unbiased view of the use of chemicals in food processing in this country. It should alleviate some of the fear about use of these agents that has existed in some quarters. On the other hand, it should aid materially in providing an understanding of the nature and extent of the problems associated with their use.

MEDICAL RESEARCH IN THE DEPARTMENT OF DEFENSE

GUEST EDITORIAL

Lowell T. Coggeshall, M.D.

Paralleling the technological development of modern weapons systems, less publicized but very important medical research is being conducted within the Department of Defense. Without effective manpower the developments in modern weapons systems could not be effectively utilized.

In the armed services man must be prepared to take his place quickly in environments where there are wide ranges of temperature, pressure, and humidity; visual problems; noise and vibration; positive and negative g-forces; noxious gases; and ionizing radiation. In addition man must be prepared to make his temporary abode among populations in foreign lands where exotic diseases are commonplace and many better known diseases, as we know them, are endemic. Man must be prepared to become acclimated and function as part of the defense team from the polar regions to the tropics and from pressures beneath the seas to the rare atmospheres of extreme altitudes, where wide latitudes of temperature, from the cold of altitude to the heat of supersonic aircraft, and where increases in cosmic radiation are encountered. Thus the modern fighting man must be prepared either to adapt himself or to have created for him an environment in which he may cope with these stresses and still function efficiently to operate modern weapons.

Well men must be aided to survive the stresses of
ronment in addition, the sick and wounded
d in order to conserve fighting
forces medical services have al-

nt of
from
. The
Assis-

challenge of these problems is being met by medical research investigators of the Department of Defense in programs of wide coverage conducted in 29 laboratories of the armed services together with contract work in universities and civilian institutions. In addition, clinical investigation is conducted in many of the armed forces hospitals not directly associated with the medical research laboratories.

These medical research laboratories of the Department of Defense vary in size, composition, and orientation in their research programs; and they have no civilian counterparts covering such a magnitude of special investigations. They are operated by the medical personnel of the Army, Navy, and Air Force, with military and civilian scientists working side by side. Five of these laboratories are located in areas outside the United States—in Egypt, Japan, Formosa, Alaska, and Puerto Rico. In addition there is a research unit in Malaya working on infectious diseases in close cooperation with the Institute for Medical Research of the Federation of Malaya, Kuala Lumpur, Malaya. Some carry on basic and applied research in special areas such as the nutrition of military personnel under stress; others limit their investigations to aviation medicine or flying equipment and clothing, or physiological and psychological problems peculiar to underwater operations. The one tri-service laboratory is devoted to development of special items of medical equipment pertinent to military medical field operations. While some of the work is of necessity classified, the majority of the research results are reported in the open literature.

Many of the units are located near university centers from which consultation may be obtained. Some have university affiliations, such as the Johnsville Acceleration Laboratory, wherein military officers are associated with and provide teaching services for the University of Pennsylvania Graduate Medical School, while selected graduate students utilize the excellent facilities of the human centrifuge to study effects of g-forces on primates, including man. Coordination of programs and projects is accomplished through a medical sciences coordinating committee in the office of Clifford C. Furnas, Assistant Secretary of Defense (Research and Development), who maintains close liaison with the office of Dr. Frank B. Berry, Assistant Secretary of Defense (Health and Medical). Civilian consultation on the programs and projects is sought through the medical division of the National Research Council, the Armed Forces Epidemiological Board, and the Advisory Panel on Medical Sciences to the Assistant Secretary of Defense (Research and Development). The present chairman of the Advisory Panel on Medical Sciences is Dr. Richard A. Kern of Philadelphia.

Of the 29 medical research laboratories in the Department of Defense, the 3 major ones—Army Medical Research Institute, Walter Reed Army Medical Center, Washington, D. C.; Naval Medical Research Institute, Bethesda, Md.; and the Aeromedical Research Laboratory, Wright Patterson Air Force Base, Dayton, Ohio—are well known to the medical profession. However, the 26 other laboratories may not be so well known, and, since one cannot outline the mission of each, in general it may be stated that the medical laboratories of the Defense Department conducting research are closely allied to hospital centers or have clinical material readily available. An example is the surgical research unit at Brooke Army Hospital near San Antonio, Texas, which specializes in research on the care and treatment of burns. Severely burned persons are flown to this unit by special evacuation teams from points throughout the United States. At the Navy Medical Research Laboratory at the Submarine Base, New London, Conn., research is devoted exclusively to submarine medicine. All prospective submarine crews are trained there, and they afford the laboratory a continuous flow of subjects for research. At the Air Force School of Aviation Medicine, Randolph Air Force Base, Texas, about 75% of the effort of the personnel of the school is in research primarily in aviation medicine. Here investigation is carried on in the physiological effects of high-speed, high-altitude acceleration and noise; neuropsychiatric factors affecting selection and classification; and air-crew effectiveness and air-crew evacuation, as well as other areas.

It is encouraging to know that this wide spectrum of research in the medical sciences is being intelligently and vigorously conducted. Opportunities for research experience in the Department of Defense laboratories are available to qualified reserve military personnel as well as to career military and civilian scientists.

FAR-REACHING STUDY AT MIDPOINT

Some 7,000 hospitals across the nation now have received questionnaires that may influence the course of medicine in the United States. Hospital construction, medical education, health insurance rates, public regard for doctors and health—all these are subject to beneficial revision when this massive five-year study is completed. The study is now at midpoint. It began late in 1953 when the A. M. A. undertook the gigantic task of measuring the total of medical service rendered to the American people by their physicians. This had never been done before. For once, there would emerge a national picture of what the patient gets for what he spends—and not the cold, misleading stroke of a statistician's pen sketching only a dollar sign.

In phase 1 of the three-point study, the A. M. A. Bureau of Medical Economic Research determined the age and sex of all hospital patients on a given day. It was a simple pair of questions, but, thanks to the earnest cooperation of hospital administrators, the answers were a series of startling revelations. They disclosed, for example, that males are the more hospitalized sex, although one-sixth of admissions were pregnant women. And the study revealed that 28% of hospital patients under 15 were in hospitals for patients with nervous or mental diseases.

Last month, the more important phase 2 of the survey began. Questionnaires were sent out to learn the age, sex, length of stay, and diagnoses for every hospitalized person discharged during the third week of this month, October, 1956. The import of this quiz sheet alone is tremendous. It will help answer such questions as: Which ailments or conditions are sending most Americans to hospitals? Which are keeping them there the longest? How many hospital beds are taken up by accident casualties, by pregnant women, by patients undergoing elective surgery (such as cosmetic)? (The survey will not accurately show the number of patients admitted to a hospital for "a rest" or for general observation.) What operative procedures seem to be predominant for specific diagnoses, and how will this knowledge contribute to medical education? How many patients are helped through diagnoses of other ailments that were hidden or unsuspected when they were admitted to the hospital—and how might this help in the training of a physician? How can the patterns thus disclosed help in the design and location of new hospitals? The figures, as if from a projector, will be able to spring into view like composite pictures of the 20 million people admitted to U. S. hospitals each year.

Next spring the huge survey is expected to be completed, with similar information asked of physicians on their patients seen in the office and in the home. When all the data are collected, correlated, and evaluated for publication late in 1958, the A. M. A. will have spent about $100,000 on this project, according to Frank G. Dickinson, Director of the Bureau of Medical Economic Research. The consequent value to U. S. physicians and the general public might be inestimable.

Again, hospital administrators are playing a key role. They are asked now to supply more data than they did in 1953, but, as the Bureau's director says, "For the well-run hospital this should be a routine copying job." The result to which they are contributing is anything but routine.

ENDOMETRIOSIS AND INFERTILITY

Endometriosis decreases the fertility of an individual, although many women conceive in spite of this complication. Fertility in normal women declines rapidly after 35 years of age. Pregnancy does not have a deleterious effect on endometriosis, for it is likely to remain quiescent or even undergo some regression. The progress of endometriosis is dependent on ovarian function, so that any measure that suppresses gonadal activity will affect the endometriosis favorably. Thus, the steroid hormones, estrogens and androgens, inhibit the function of the anterior lobe of the pituitary and suppress ovarian function. A diagnosis of endometriosis is usually made on pelvic examination, which will reveal an enlarged adherent ovary on one or both sides and thickening and fixation in the cul-de-sac and rectovaginal septum. In classic cases bluish cysts can often be visualized in the posterior vaginal cul-de-sac with the aid of a speculum. A curettage provides no information concerning endometriosis, but it will rule out pathology of the endometrium such as carcinoma. A positive diagnosis of endometriosis in some cases cannot be made prior to laparotomy. However, the history of progressive dysmenorrhea and typical pelvic findings leave little doubt in most cases. If the patient does become pregnant and a repeat cesarean section is carried out, the adnexa and cul-de-sac may be inspected for the presence of endometriosis, and if it is extensive cesarean hysterectomy may be considered. If surgery is indicated in progressive endometriosis in young women, the present tendency is to be as conservative as possible, particularly in the individual who wishes more children.

ORGANIZATION SECTION

ANNUAL A. M. A. MEETING IN NEW YORK, JUNE 3-7, 1957

The Annual Meeting of the American Medical Association will be held in New York, June 3-7, 1957. The Scientific Exhibit and several meeting halls will be housed in the new, air-conditioned Coliseum, along with Registration and the Technical Exposition. Other meeting halls will be held in hotel ballrooms in the adjacent vicinity of the Coliseum.

Persons desiring to read papers before one of the sections should communicate with the secretary of that section. Similarly, persons desiring space in the Scientific Exhibit should obtain an application for space from the exhibit representative or from the Secretary of the Council on Scientific Assembly. The Scientific Program is well under way, and Dec. 17, 1956, has been set for the deadline for the receipt of requests to read papers and applications to present scientific exhibits.

Additional information may be obtained from the Secretary of the Council on Scientific Assembly, American Medical Association, 535 N. Dearborn, Chicago, 10.

Following are the secretaries and representatives to the Scientific Exhibit from the various sections:

Anesthesiology

Secretary—Daniel C. Moore, M.D., 1118 Ninth Ave., Seattle 1.

Exhibit Representative—Edwin L. Rushia, M.D., University Hospital, Augusta, Ga.

Dermatology

Secretary—Clarence S. Livingood, M.D., Henry Ford Hospital, Detroit 2.

Exhibit Representative—Stanley E. Huff, M.D., 636 Church St., Evanston, Ill.

Diseases of the Chest

Secretary—Burgess L. Gordon, M.D., Woman's Medical College of Pennsylvania, Philadelphia 29.

Exhibit Representative—Edwin R. Levine, M.D., 109 N. Wabash Ave., Chicago 2.

Experimental Medicine and Therapeutics

Secretary—Elliot V. Newman, M.D., Vanderbilt University Hospital, Nashville 5, Tenn.

Exhibit Representative—Joseph F. Ross, M.D., University of California Medical Center, Los Angeles 24.

Gastroenterology and Proctology

Secretary—William H. Dearing, M.D., 200 First St. S.W., Rochester, Minn.

Exhibit Representatives—Willard H. Bernhoft, M.D., 537 Delaware Ave., Buffalo 2, and George Gordon McHardy, M.D., 3636 St. Charles Ave., New Orleans 15.

General Practice

Secretary—E. I. Baumgartner, M.D., 25 Alder St., Oakland, Md.

Exhibit Representative—I. Phillips Frohman, M.D., 2924 Nichols Ave S.E., Washington 20, D. C.

Internal Medicine

Secretary—Rudolph H. Kampmeier, M.D., Vanderbilt University School of Medicine, Nashville 5, Tenn.

Exhibit Representative—Henry T. Ricketts, M.D., 950 E. 59th St., Chicago 37.

Laryngology, Otology and Rhinology

Secretary—Hugh A. Kuhn, M.D., 112 Rimbach St., Hammond, Ind.

Exhibit Representative—Walter E. Heck, M.D., Stanford University Hospitals, San Francisco 15.

Military Medicine

Secretary—Capt. Cecil L. Andrews, M. C., U. S. N., Bureau of Medicine and Surgery, Department of the Navy, Washington 25, D. C.

Exhibit Representative—Col. Frank M. Townsend, M. C., U. S. A. F., Armed Forces Institute of Pathology, Washington 25, D. C.

Nervous and Mental Diseases

Secretary—Adolph L. Sahs, M.D., University Hospitals, Iowa City.

Exhibit Representative—Benjamin Boshes, M.D., Northwestern University Medical School, 303 E. Chicago Ave., Chicago 11.

Obstetrics and Gynecology

Secretary—Keith P. Russell, M.D., 511 S. Bonnie Brae St., Los Angeles 57.

Exhibit Representative—Frederick H. Falls, M.D., P. O. Box 47, River Forest, Ill.

Ophthalmology

Secretary—Harold G. Scheie, M.D., 313 S. 17th St., Philadelphia 3.

Exhibit Representative—Frank W. Newell, M.D., 950 E. 59th St., Chicago 37.

Orthopedic Surgery

Secretary—H. Herman Young, M.D., 200 First St. S.W., Rochester, Minn.

Exhibit Representative—James I. Kendrick, M.D., 2020 E. 93rd St., Cleveland 6.

Pathology and Physiology

Secretary—Hugh A. Edmondson, M.D., 1200 N. State St., Los Angeles 33.

Exhibit Representative—Samuel A. Levinson, M.D., 808 S. Wood St., Chicago 12.

Pediatrics

Secretary—Wyman C. C. Cole Sr., M.D., 3011 W. Grant Blvd., Detroit 2.

Exhibit Representative—F. Thomas Mitchell, M.D., Le Bonheur Children's Hospital, Memphis 5, Tenn.

Physical Medicine

Secretary—Walter J. Zeiter, M.D., 2020 E. 93rd St., Cleveland 6.

Exhibit Representative—Donald A. Covalt, M.D., 400 E. 34th St., New York 16.

Preventive Medicine
Secretary—Frank Princi, M.D., Kettering Laboratory, University of Cincinnati College of Medicine, Cincinnati 19.
Exhibit Representative—Paul A. Davis, M.D., 633 E. Market St., Akron 4, Ohio.

Radiology
Secretary—Gustaf E. Lindskog, M.D., 333 Cedar St., New Haven 11, Conn.
Exhibit Representative—Richard H. Chamberlain, M.D., 3400 Spruce St., Philadelphia 4.

Urology
Secretary—Thomas A. Morrissey, M.D., 40 E. 61st St., New York 21.
Exhibit Representative—Milton M. Coplan, M.D., 550 Brickell Ave., Miami 32, Fla.

PROGRESS ON A. M. A. SESSION IN SEATTLE

Plans are progressing for the A. M. A. Clinical Session in Seattle on Nov. 27-30. It is the first time the A. M. A. has met in Seattle. Under the general chairmanship of M. Shelby Jared of Seattle, several committees have formulated the program, after conferences with the A. M. A.'s Council on Scientific Assembly. Hale Haven's Scientific Program Committee reports a tremendous response to the call for volunteers to present scientific papers. Over 140 abstracts have been submitted, and only 40 papers can be presented. The program was planned for the general practitioner, and his everyday problems. Panel discussions also are being developed.

F. A. Tucker's Television Program Committee has drafted a series of "wet and dry" clinics on a closed television circuit to point up such diverse subjects as cesarian section, vein stripping, "the G. I. Bleeder," and chest emergencies. A panel discussion on the aging population is to be shown to the public on an open television channel. Sydney Hawley's Entertainment Committee is planning menus, decorations, favors, and a sparkling program for the House of Delegates dinner. Mrs. Roger Anderson and Mrs. Lester Henderson are planning events for the Auxiliary. Boat trips, luncheons, shopping tours, and symphony concerts are on the agenda.

A series of films on medicolegal problems will be produced by the pharmaceutical firm of William S. Merrell Company of Cincinnati in cooperation with the A. M. A. Law Department. The first film, dealing with the doctor as a medical expert witness, will be previewed at the A. M. A. Clinical Session in Seattle, Nov. 27-30. This film will be available for showings at state and county medical society meetings after Dec. 15.

Wilbur Watson, in charge of housing and transportation, and his committee are checking accommodations. Seattle's hotels have assured him there are plenty of first-class rooms to accommodate all visitors. (Get your reservations in early.) The Washington State Medical Association Office is handling all the details. Staff members are being aided by Mr. James Borgen, Executive Secretary, Kitsap County Medical Society, and Mr. William Ramsey, Executive Secretary, King County Medical Society. The usual high caliber of commercial and scientific exhibits is expected. Plan to be in Seattle Nov. 27-30. It will be well worth your while. For hotel reservations, write Dr. Wilbur Watson, Chairman, A. M. A. Housing Bureau, 315 Seneca St., Seattle.

UNIVERSITY OF WASHINGTON MEDICAL SCHOOL AT SEATTLE

The territorial legislature authorized the establishment of schools of medicine and law at the University of Washington in 1885, and the minutes of the Board of Regents of the University for October, 1885, include a report of a special committee on the organization of the proposed medical school. It includes the names of proposed faculty personnel, the departments to be developed, the general outline of the curriculum, and the tuition to be charged. What happened to these plans is not clear.

About the time of the first World War, interest in the development of a medical school at the university increased, and, while during that period instruction was established in anatomy, physiology, bacteriology, pathology, biochemistry, and pharmacology, it was not formally organized into a two-year basic medical science course equivalent to the first two years of medicine. During the next two and a half decades, no energetic efforts were made to establish either a two-year basic medical science or four-year medical school program.

In 1944-1945 there was sudden greatly increased interest spearheaded by the medical profession, with the support of the university authorities. The dental profession joined hands with the medical profession and the university authorities, and, during the 1945 session of the legislature, authorization was given for the establishment of medical and dental schools at the University of Washington in Seattle. Administrative officers were selected for the new schools late in 1945, and progress was rapid enough to permit admission of 50 students to the entering class of each school in the fall of 1946. Instruction during the first three years was conducted in temporary quarters, while the current physical facilities were being developed. The basic medical science facilities were developed so as to meet not only the needs of the new professional schools but also other university disciplines where such instruction is needed.

Although the teaching hospital facilities at the university are still in the developmental stage, the medical school, in cooperation with such institutions as the King County Hospital, the Veterans Administration Hospital, the U. S. Public Health Service Hospital, the Children's Orthopedic Hospital, the Firland Sanatorium, certain private hospitals, state institutions, and local as well as state agencies, has been able in the 10 years of its existence to develop an institution that has won high national recognition in both teaching and research. Physicians attending the midwinter session of the American Medical Association in Seattle will find a visit to the new medical school an interesting and worthwhile experience.

PROCEEDINGS OF THE CHICAGO MEETING

ABSTRACT OF PROCEEDINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION AT THE ANNUAL MEETING IN CHICAGO, ILL., JUNE 11-15, 1956

(Continued from page 505)

Introduction of Resolutions

The Speaker called for the introduction of resolutions as numbered.

No. 1, Resolution on Service Membership for Reserve Officers

Dr. Charles L. Leedham, for the Section on Military Medicine, introduced the following resolution, which was referred to the Reference Committee on Medical Military Affairs:

WHEREAS, The American Medical Association Constitution and Bylaws make no provision for any type of American Medical Association membership for the military reservist who is on temporary active duty with the Armed Forces, the Public Health Service or the Veterans Administration unless the physician had previously held membership through a local county and state medical society, and

WHEREAS, A limited number of state and county medical societies have provided some type of local membership to qualify the physician absent in military service for American Medical Association membership, and other state and county societies have refused to take such action; and

WHEREAS, It is extremely desirable to afford all physicians in the military services, whether permanent or temporary, the opportunity to become members of the American Medical Association, therefore be it

Resolved, That the House of Delegates amend the provisions of the Bylaws *so that membership can be made available for the reserve officers of the military services* on short term duty by changing Section 2, Chapter I of the Bylaws of the American Medical Association as follows. That the subclassification "(A)" be inserted after the title words "Service Members" and before the word "Regular" making the present Section 2, as written, the first of two parts, and that the following be added as the second part "(B) Commissioned medical officers of the reserve components of the organizations listed in Section 2(A) above are accorded the same rights and privileges as regular officers, insofar as membership is concerned, during their term of active duty plus one year or until they become members of a constituent association of the American Medical Association whichever is sooner."

REPORT OF REFERENCE COMMITTEE ON MEDICAL MILITARY AFFAIRS

Dr. William C. Chaney, Chairman, Tennessee, submitted the following report, which was adopted:

Your reference committee supports the principle expressed in Resolution No. 1 by the Section on Military Medicine and agrees that it is extremely desirable to afford all physicians in the military services, whether permanent or temporary, the opportunity to become members of the American Medical Association. However, the resolution as proposed presents difficult administrative problems. Further, the committee is cognizant of the prerogative of county medical societies in *selecting their own* members. Therefore, your committee recommends that the resolution not be adopted at this time.

Your committee does recommend that the Secretary and General Manager of the Association be authorized to meet with representatives designated by the Surgeons General of the Army, Navy, and Air Force to study *and make* recommendations on this subject to the House of Delegates at the 1956 Clinical Meeting.

Resolutions No. 2 to 5

Dr. Truman C. Terrell, for the Texas delegation, introduced the following Resolutions Nos. 2 to 5, each of which was referred to the Reference Committee on Legislation and Public Relations:

No. 2. Resolution on the Narcotic Traffic

PREAMBLE

Senate Resolution 67, adopted March 18, 1955, authorized the first [illegible] investigation of the narcotics traffic with the aim to find "ways and means of improving the Federal Criminal Code and other laws and enforcement procedures dealing with possession, sale, and transportation of narcotics, marihuana, and similar drugs." This task was assigned to the Senate Subcommittee on Improvements in the Federal Criminal Code, the Hon. Price Daniel, junior Senator from Texas, Chairman. This subcommittee has found that, among other things, the United States has more narcotic addicts, both in total numbers and population-wise, than any other country in the western world that the illicit drug traffic has tripled in the United States since World War II; and that drug addiction is responsible for approximately 50 per cent of all crimes committed in the larger metropolitan areas. *This subcommittee* now is drafting specific legislation concerning improvement of narcotic control.

Resolved, That the House of Delegates of the American Medical Association recommend to Congress that appropriate legislation be enacted to improve narcotic control, and that copies of this resolution be sent to the President of the United States, members of his Cabinet, and all members of Congress.

No. 3. Resolutions on Opposition to S. 1323 Which Would Subsidize Medical Schools

PREAMBLE

A Supreme Court decision has stated that "It is hardly lack of due process for the Government to regulate that which it subsidizes." The American Medical Association consistently has held the opinion that federal aid is a "dangerous device" and so testified before the Health Subcommittee of the Senate Labor and Public Welfare Committee on May 6, 1955. More doctors of medicine now are being graduated from the 80 medical schools of this country than at any time since these schools were approved, and the quality of medical training has consistently improved until now it is the finest offered anywhere in the world. This high level of medical training and this large number of graduates from medical schools have been attained with little or no federal subsidy. *Incidentally*, it is recognized that the federal government is already burdened with many billions of dollars of public debt, yet S. 1323 carries an appropriation of 250 million dollars, which would further increase this debt. *The federal government*, under the provisions of S. 1323, would have the legal right to subsidize the cost of maintenance of the new *facilities* built under its provisions by allowing the applicant *to set aside 20 per cent* of the federal grant for "permanent endowment." Past experience has shown that the stipulations of a "temporary *emergency*" and "*single grant*" offer no protection against perpetuation, since the same philosophy was incorporated in the Hill-Burton laws which have recently been extended to 1960.

Resolved, That the House of Delegates of the American Medical Association hereby expresses strong opposition to S. 1323 notwithstanding *former positions or interpretations* of the bill by the American Medical Association, because it is apparent that S 1323 represents a major step toward *the complete socialization* of medical education and practice in this country, and be it further

Resolved, That copies of this resolution be sent to the President of the United States, members of his Cabinet, and all members of Congress

No. 4. Resolutions on Opposition to H. R. 483 Authorizing Armed Forces to Commission Osteopaths

PREAMBLE

It is apparent that the commissioning of *osteopaths* in the armed forces would force servicemen of this country to submit to general medical and surgical care of osteopaths. Standards of osteopathic care are not regarded as equal to those of care by regular *medical* practitioners Those who practice osteopathy do so without the educational background and clinical instruction received by graduates of accredited schools of medicine. It is our belief that the appointment of osteopaths as medical officers would endanger the *health and welfare* of our military personnel. It is also our belief that the appointment of osteopaths would contribute to the demoralization of career officers in the military medical service and great harm would be *done* to the fine military civilian consultant program, since an ethical doctor of medicine cannot *voluntarily consult* with osteopaths. This development would doubtless result in widespread resignations of medical officers. *It also* should be recognized that the appointment of osteopaths would endanger the accreditation of residency and intern training programs in military hospitals

Resolved, That the House of Delegates of the American Medical Association does hereby go on record as opposing most vigorously H. R. 483, which would authorize the Armed Forces to commission osteopaths, and be it further

Resolved, That copies of *this resolution* be sent to the President of the United States, members of his Cabinet, and all members of Congress

No. 5. Resolution on Accelerated Tax Write-Off for Private Hospital Expansion and Construction

PREAMBLE

National surveys made by such eminent authorities as Dr. John W. Cronin, Chief of the Division of Hospital Facilities of the Public Health Service, have shown that there is a rapidly increasing deficit of hospital facilities throughout the United States in spite of millions of dollars expended through the Hill-Burton Act and by various municipalities, churches, and private or individual enterprise. The Public Health Service budget for 1956 includes $125,000,000 of available funds for grants for hospital construction. Even if this full amount should be utilized, however, there would still be a deficit of over 800,000 hospital beds now needed in this country.

It is recalled that during the recent Korean conflict the Office of Defense Mobilization was set up, among other purposes, to stimulate private industry to build or to expand facilities for supplying material needed for mobilization and for the general safety, security, and well-being of our country. To accomplish this purpose, an accelerated tax write-off was allowed for such construction in many fields of industry. The need for more hospital beds in the United States is likewise a definite factor in the general safety, security, and well-being of our country. Private physicians or groups of physicians would much prefer to expand their hospital facilities at their own expense rather than to depend upon federal grants. If hospital construction can be financed by private enterprise, there will be effected a tremendous saving to the federal government. If provision were to be made for an accelerated tax write-off program to apply in the construction of private hospitals, owners of such hospitals would be greatly encouraged and stimulated to make needed expansions or to construct entirely new hospital facilities.

Resolved, That the House of Delegates of the American Medical Association recommend to Congress the enactment of proper legislation to provide for the above-described procedure of accelerated tax write-off for the costs of new construction or expansion of private hospitals, and that copies of this resolution be sent to the President of the United States, members of his Cabinet, and all members of Congress.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. Willis H. Huron, Chairman, Michigan, presented the following report, which, after discussion and after a motion to substitute the original Resolution No. 3 for the committee report thereon was lost, was adopted:

Resolution No. 2 on the Narcotic Traffic.—Your reference committee has studied this resolution, and although it approves the specific principle involved, it fears that because of the many problems and possible complications, this resolution should be referred to the Committee on Legislation for further study.

Resolution No. 3 on Opposition to S. 1323.—Your committee appreciates the intent with which this resolution was introduced, but at the same time feels that there are many economic and geographical factors involved which might not make this resolution practical on a national level. Inasmuch as no evidence was offered to this committee to justify a change in the previously declared policy of the House of Delegates, your committee recommends that the previous action of this House be reaffirmed and this resolution be not adopted.

Resolution No. 4 on Opposition to H. R. 483 Authorizing Armed Forces to Commission Osteopaths.—Since the Committee on Legislation and our Washington Office have been very active in their efforts to oppose this legislation, your committee feels that continued efforts will be made without the need of this specific reference. It feels that the purpose of this resolution has already been carried out, and that this resolution is unnecessary at the present time. Your committee recommends that this resolution be not adopted.

Resolution No. 5 on Accelerated Tax Write-Off for Private Hospital Expansion and Construction.—Your reference committee agrees with the intent and principle contained in this resolution, and recommends its referral to the Committee on Legislation. Your reference committee is now cognizant of what may be a well-known fact in Texas, that the 27 per cent depletion cannot be applied to accelerated tax write-offs for private hospitals.

No. 6. Resolution on Medical Care for Civil Service Employees

Dr. Truman C. Terrell, for the Texas delegation, introduced the following resolution, which was referred to the Reference Committee on Insurance and Medical Service:

PREAMBLE

Civilian employees, under Civil Service, of various federal military installations are required to undergo yearly physical examinations (including eye examination, chest x-ray, EKG, routine laboratory procedures) by government employees at taxpayers expense. This represents another intrusion into the private practice of medicine and conceivably justifies some usage of physicians drafted into the military service; now therefore be it

Resolved, That the House of Delegates of the American Medical Association strongly oppose this practice and that copies of this resolution be sent to the President of the United States and to all members of Armed Services Committees of the United States Senate and House of Representatives.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. John K. Glen, Chairman, Texas, read the following report, which was adopted:

Your reference committee received considerable discussion on Resolution No. 6 on Medical Care for Civil Service Employees, introduced by the Texas delegation. It was felt by the reference committee that since the examination of Civil Service employees by government military medical personnel at taxpayers' expense is a *fait accompli* under Public Law 658 of the 79th Congress, 1946, and under Presidential directives of 1950, it would little avail the House of Delegates to "strongly oppose" the practice. However, because such a practice might conceivably justify some use of physicians drafted into military service, your committee recommends that this matter be referred to the Council on Medical Service that its Committee on Federal Medical Services might investigate this matter and report back to the House at the 1956 Interim Meeting.

No. 7. Resolution on Amendment to Principles of Medical Ethics, Chapter I, Section 12

Dr. Ezra A. Wolff, for the Medical Society of the State of New York, introduced the following resolution, which was referred to the Reference Committee on Amendments to the Constitution and Bylaws:

WHEREAS, The Principles of Medical Ethics of the American Medical Association are stated in more general terms than the Principles of Professional Conduct (or Ethics) of the constituent state medical societies and/or associations; and

WHEREAS, Difference in local custom and practice often makes it necessary for the Principles of Professional Conduct (or Ethics) of the constituent state society or association to be more specific and stringent than the Principles of Medical Ethics of the American Medical Association; and

WHEREAS, The enforcement of the constituent state society's Principles of Professional Conduct (or Ethics) is a function of the state medical society; and

WHEREAS, Appeals by members against decisions of the constituent state society are only subject to review by the Judicial Council of the American Medical Association when questions of law or procedure are involved; now therefore be it hereby

Resolved, That the Principles of Medical Ethics of the American Medical Association be amended so as to add to Chapter I, which deals with general principles, a Section 12 which should read as follows:

"Sec. 12.—When the Principles of Professional Conduct (or Ethics) of a constituent state medical society or association are more specific or stringent concerning a matter of ethics than are the Principles of *Medical Ethics* of the American Medical Association, then the Principles of Professional Conduct (or Ethics) of the constituent state medical society or association shall be binding on all of its members if it is not inconsistent or in conflict with the Constitution and Bylaws of the American Medical Association."

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO THE CONSTITUTION AND BYLAWS

Dr. Jay J. Crane, Chairman, Section on Urology, read the following report, which was not adopted, and the Speaker ruled that in accordance with the provisions of the Bylaws regarding amendment of the Principles of Medical Ethics—adopted at this session of the House—the proposed amendment presented in Resolution No. 7 would be referred to the Council on Constitution and Bylaws.

Resolution No. 7.—Your committee also received Resolution No. 7 from the Medical Society of the State of New York recommending an amendment to the Principles of Medical Ethics in which it was recommended that a new Section 12 be added to

Chapter I of the Principles of Medical Ethics. Since there is a complete revision of the Principles of Medical Ethics under present consideration, your committee recommends that Resolution No. 7 be not approved.

No. 8. Resolutions on Opposition to Increase in American Medical Association Dues

Dr. John F. Burton, for the Oklahoma delegation, introduced the following resolutions, which were referred to the Reference Committee on Reports of Board of Trustees and Secretary:

Whereas, It has come to the attention of the Oklahoma State Medical Association that the House of Delegates of the American Medical Association may discuss an increase in American Medical Association dues at its meeting in June, 1956, at Chicago; and

Whereas, It is understood that only 18 of the 53 constituent state and territorial medical associations have compulsory payment of the annual membership dues of the American Medical Association; and

Whereas, It is understood that approximately 30 per cent or more of American doctors who are members of county and state medical associations do not pay American Medical Association dues; now therefore be it

Resolved, That the House of Delegates of the Oklahoma State Medical Association firmly opposes any increase in the annual membership dues of the American Medical Association, in 1956 or any future time, so long as the payment of American Medical Association dues continues to remain optional with the great majority of the members of constituent state and territorial medical associations, and has instructed its delegates to so vote on all questions calling for an increase of American Medical Association dues; and be it further

Resolved, That this situation is inequitable, and that any necessary increase in American Medical Association dues income be derived from those doctors who are not meeting their obligation in this respect by refusing to pay such dues.

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Dr. Woodruff L. Crawford, Chairman, Section on Pediatrics, presented the following report, which was adopted:

Opposition to Increase in AMA Membership Dues (Resolution No. 8).—This resolution, introduced by the Oklahoma delegation, was considered by your committee. Inasmuch as no increase in dues is contemplated at this time, your reference committee recommends that no action be taken on this resolution.

No. 9. Resolutions on Veterans Affairs

Dr. John F. Burton, for the Oklahoma delegation, introduced the following resolutions, which were referred to the Reference Committee on Insurance and Medical Service:

Whereas, in many Veterans Administration hospitals the fulltime medical staff employees are rendering bills to patients treated in the veterans hospitals who are covered by Workmen's Compensation insurance and also by private medical and hospital insurance; and

Whereas, These fees collected are placed in various funds for the benefit of the staff; and

Whereas, These benefits could well be supplied by the individual employee from his salary as his brother physicians in private practice are compelled to do; and

Whereas, According to Veterans Administration Regulation 6047-D 1, only veterans who are financially unable to pay are eligible for treatment of non-service-connected disability in veterans hospitals; now therefore be it

Resolved, That the Oklahoma State Medical Association considers these procedures unlawful and in direct violation of Veterans Administration Regulation 6047-D 1; and be it further

Resolved, That the Oklahoma State Medical Association request the Board of Trustees of the American Medical Association to appoint immediately a committee to confer with the Veterans Administration to stop this vicious procedure and report back to the House of Delegates at its next meeting.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. John K. Glen, Chairman, Texas, submitted the following report, which, after discussion, and after a substitute motion that the Speaker appoint a committee to confer with the Veterans Administration to stop the procedures described in Resolution No. 9 was lost, was adopted:

Resolution No. 9 on Veterans Affairs.—Your reference committee listened to much discussion of this resolution. It learned again that, under the present laws of the United States, no statement that a veteran is able to pay for his medical care and/or hospitalization can supersede his own statement that he cannot pay.

Resolution No. 9 is so worded that the resolves do not actually apply to the House of Delegates. In spite of this the reference committee did not quibble about the wording of the resolution, but it did feel that if the Oklahoma delegation has valid evidence of unlawful acts on the part of directors or of employees of veterans hospitals, such evidence should be presented to the proper state or federal authorities in Oklahoma. This is so particularly because this House of Delegates does not have such evidence. Your committee recommends that Resolution No. 9 be not approved.

No. 10. Resolution on Proposed Amendment to Bylaws Concerning Composition of Board of Trustees

Dr. Millard D. Hill, North Carolina, introduced the following resolution, which was referred to the Reference Committee on Amendments to the Constitution and Bylaws:

Resolved, That Chapter XVI, Section 1, of the Bylaws be amended by the addition of the following sentence: "The Vice President, Treasurer, Speaker and Vice Speaker of the House of Delegates shall be ex officio members of the Board with all the rights and duties of the Board without the right to vote."

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO THE CONSTITUTION AND BYLAWS

Dr. Jay J. Crane, Chairman, Section on Urology, read the following report, which was adopted:

Resolution No. 10.—Your committee received a resolution submitted by Dr. Millard D. Hill, delegate from North Carolina, on the subject, "Proposed Amendment to Bylaws Concerning Composition of Board of Trustees," resolving that Chapter XVI, Section 1, of the Bylaws be amended.

Your reference committee recommends the adoption of this proposed amendment to the Bylaws.

No. 11. Resolutions on Straight Internships

Dr. Ralph E. Campbell, Section on Obstetrics and Gynecology, introduced the following resolutions, which were referred to the Reference Committee on Medical Education and Hospitals:

Whereas, Obstetrics and gynecology has traditionally been considered as one of the four major branches of internship training; and

Whereas, The American Medical Association and its Council on Medical Education and Hospitals disapproved all straight internships except those in medicine, surgery, pathology, and pediatrics; and

Whereas, This discriminatory policy will, in many hospitals, eliminate all interns in obstetrics and gynecology, result in deterioration of patient care, and discourage the usual flow of recent graduates from internship through residency training; therefore be it

Resolved, That the American Medical Association through its Council on Medical Education and Hospitals review and reconsider the present policy in the matter of straight internships; and be it further

Resolved, That the American Medical Association and its Council on Medical Education and Hospitals abolish all straight internships in all hospitals and in all medical specialties and for all graduated medical students; and be it further

Resolved, That straight internships in obstetrics and gynecology be continued until such time as all straight internships in all medical specialties are simultaneously abolished.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. George S. Klump, Chairman, Pennsylvania, presented the following report, which was adopted after discussion:

Resolutions Nos. 11 and 38.—These resolutions were considered together at the hearing because both deal with the type of internship that may provide the better preparation for medical practice, rotating or straight. There was a surprising unanimity of opinion that a rotating internship was preferred. Your committee also reviewed a portion of the Annual Report on Internships and Residencies and the Medical Licensure Statistics for 1955. Fourteen boards now require a rotating internship for licensure.

Your reference committee believes that there is a growing body of opinion within the profession in favor of a rotating internship. It also recognizes the difficulties involved and the dangers to some established educational programs were action taken precipitously to disapprove straight internship, which are about 10% of the total number now approved. Your committee recommends the following substitute resolution for resolutions 11 and 38.

Resolved, (1) That the Council on Medical Education and Hospitals be requested to increase its efforts to encourage rotating internships rather than straight internships in all hospitals approved for the latter, and (2) that a report of the results of this effort be submitted annually.

No. 12. Resolution on Establishment of Inhalation Therapy Schools

Dr. W. P. Anderton, for the Medical Society of the State of New York, introduced the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

Whereas, There are insufficient numbers of physicians and technicians who have been well-trained in the techniques of inhalation therapy in many parts of the United States of America, and

Whereas, The effective use of inhalation therapy may be the determining factor between life and death in such conditions as heart failure, coronary artery disease, asthma, atelectasis of the lungs in newborn infants, postoperative atelectasis, pneumonia, pulmonary edema, emphysema, cerebral thrombosis, and others, and

Whereas, "Standards of Effective Administration of Inhalation Therapy" were published in The Journal of the American Medical Association of Sept 2, 1950, Vol 144, pp 25-34, and

Whereas, "Essentials of an Acceptable School for Inhalation Therapy Technicians" were published in the New York State Journal of Medicine of April 15, 1956, Vol. 56, No 8, p 1319, therefore be it

Resolved, That the Council on Medical Education and Hospitals is hereby requested to endorse such or similar "Essentials" and to stimulate the creation of schools of inhalation therapy in various parts of these United States of America.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr George S. Klump, Chairman, Pennsylvania, submitted the following report, which was adopted.

Resolution No. 12.—Your reference committee approves this resolution in principle and recommends that it be referred to the Council on Medical Education and Hospitals.

No. 13. Resolution on Reimbursement for Collecting American Medical Association Dues

Dr. Charles H. Loughran, for the Medical Society of the State of New York, introduced the following resolution, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

Whereas, The House of Delegates of the Medical Society of the State of New York on May 9, 1956, adopted the report of its Reference Committee on Report of Council Part XII, which stated in part "We are concerned to note that the collection of A.M.A dues continues to be an expense to the Society and strongly urge our Delegates to the A.M.A. to take proper steps to rectify this, either by full reimbursement by the A.M.A. to the Society, or by direct collection by the A.M.A. of its own dues", and

Whereas, The collection of American Medical Association dues in 1955 cost the Medical Society of the State of New York $8,165.37, and

Whereas, The Medical Society of the State of New York received for expenses one half of one percent of the dues collected from the American Medical Association, to wit $2,255.96, and

Whereas, This causes a loss for the year 1955 of $5,909.41 to the Medical Society of the State of New York, therefore be it

Resolved, That the Board of Trustees of the American Medical Association be requested by this House of Delegates to have a study made by certified public accountants which will encompass the collection of American Medical Association dues by state and county societies and associations, with the hope that an equitable method of reimbursement of expenses will be recommended

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Dr. Woodruff L. Crawford, Chairman, Section on Pediatrics, submitted the following report, which was adopted:

Reimbursement for Collecting American Medical Association Dues (Resolution No. 13).—This resolution introduced for the Medical Society of the State of New York was carefully considered. Dr. Charles Loughran of the New York delegation and others appeared before the committee in support of this resolution and submitted a statement of collection expenses of that state society.

Your reference committee believes this whole question of expenses of collecting American Medical Association dues requires further study, inasmuch as serious dissatisfaction exists in certain areas. We therefore, support the intent of this resolution and recommend that this House of Delegates authorize the Board of Trustees to institute a study which will result in a fair and equitable reimbursement to all medical societies and associations for expenses incurred in collection of American Medical Association dues.

No. 14. Resolutions on Health Check-Up Week for Physicians

Dr. Joseph D. McCarthy, Nebraska, introduced the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

Whereas, The conservation of the health and the logevity of physicians have been materially imperiled because of the lack of a concerted effort on their part to be informed of their individual emotional and physical shortcomings by confreres on a professional basis, and

Whereas, Longevity is comparatively greater among a considerable number of other groups of people than among those of the medical profession, and

Whereas, The health of physicians is a precious resource of communities because of their ability to conserve the health of the people, but by neglect of their own health in too many instances their ministrations have been lost, and

Whereas, Physicians urge all laymen to have periodic examinations for the purpose of detecting disease in its incipiency, and

Whereas, Urging citizens to follow through on such a program and not adopting a similar program for themselves is not an exemplification of good preventive medicine, therefore be it

Resolved, That the House of Delegates of the American Medical Association designate a "Physicians' Health Check-Up Week" for its members, they to present themselves during that week for a history, physical examination, and clinical laboratory and radiologic procedures as well as any necessary consultations, and be it further

Resolved, That hospitals having facilities necessary to complete such studies be selected as examination centers, and that details incident to this program be outlined by the appropriate committees of the respective state medical associations for the guidance of all concerned, and be it further

Resolved, That the American Medical Association urge the accomplishment of this project through its constituent associations during a week to be designated by the House of Delegates of the American Medical Association.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Joseph C. Griffith, Chairman, Wisconsin, read the following report, which was adopted.

Resolution No. 14.—Pertaining to Establishment of a National Health Check-Up Week for Physicians.—Your committee is in agreement with the intent of this proposal, but is of the opinion that it could be more successfully carried out on a county or district level rather than by a "National Week".

No. 15. Resolutions on Undesirable Activities of Pharmaceutical Manufacturers

Dr. James Z. Appel, for the Pennsylvania delegation, introduced the following resolutions, which were referred to the Reference Committee on Amendments to the Constitution and Bylaws:

Whereas, A high ethical code has for many centuries afforded patients and the community a high standard of medical practice, and

Whereas, It is part of our medical code to exert some control over the ethical standards of all persons and organizations contributing to the care of the ill, and

Whereas, Some undesirable activities by groups related to the welfare of such persons are occurring; and

Whereas, Medicine in its efforts to protect the public condemns the over-enthusiastic and premature reports of medical treatments; and

Whereas, There is an increasing trend for publicizing prematurely in nonmedical publications the discovery of new drugs before they have been fully tested or even are generally available for use by physicians; and

Whereas, There is a growing tendency for pharmaceutical oragnizations to spend large sums of money entertaining members of medical societies; and

Whereas, There is also a growing tendency for these firms to offer funds for the training of residents and fellows in teaching hospitals in return for which research projects of new drugs and their ultimate publicity is implied; and

Whereas, Many faculty members of schools of medicine are in the employment of manufacturing pharmaceutical firms; therefore be it

Resolved, That these developments offer inherent dangers to advancement in medicine and lower the prestige of the practice of medicine; and be it further

Resolved, That the Board of Trustees of the American Medical Association should consider the formulation of a policy concerning relations between pharmaceutical firms and the medical profession, as well as the public, in respect to premature publicity concerning drugs, the granting of subsidies to medical meetings, and other allied matters.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO THE CONSTITUTION AND BYLAWS

Dr. Jay J. Crane, Chairman, Section on Urology, presented the following report, which was adopted:

Resolution No. 15.—Resolution No. 15, relating to undesirable activities of pharmaceutical manufacturers was referred to this reference committee. Your committee feels that Resolution No. 15 should be not approved, and in lieu thereof recommends adoption of the following substitute resolution:

Whereas, In recent years events have indicated the necessity for a closer liaison between the pharmaceutical manufacturer and the American Medical Association; and

Whereas, In view of the tremendous number of new drugs being developed and the expanding research programs in medical colleges, clinics, and hospitals being financed by the drug industry, it is imperative that the manufacturer and the medical profession develop cooperatively guiding principles which will protect the American people from being subjected to the premature release of information pertaining to new products or techniques; and

Whereas, Competition within the pharmaceutical industry has become extremely keen so that in the advertising of their products drug manufacturing firms have been forced into the expenditure of larger and larger sums of money and in increasingly broader fields of advertising; therefore be it

Resolved, That the Board of Trustees of the American Medical Association appoint a liaison committee to meet with representatives of the pharmaceutical manufacturers to accomplish this objective.

No. 16. Resolutions on American Medical Association Regional Meeting

Dr. Eustace A. Allen, for the Medical Association of Georgia, introduced the following resolutions, which were referred to the Reference Committee on Reports of Board of Trustees and Secretary:

Whereas, The American Medical Association offers to physicians an excellent scientific, ethical, legal, and public relations program twice each year; and

Whereas, Many physicians for various reasons cannot avail themselves of these programs; and

Whereas, All physicians need to know the many problems facing medicine today; and

Whereas, A closer relationship among physicians, medical societies, and allied organizations is essential to preserve our high medical standards; and

Whereas, The best way to accomplish this is through education, open forums, and personal contact; therefore be it

Resolved, That the American Medical Association through its Board of Trustees be asked to institute a series of small regional two-day meetings to supplement these semi-annual meetings. If these regional meetings meet with initial success, it is possible that the interim session, at the discretion of the Board of Trustees or the House of Delegates, could then be eliminated; and be it further

Resolved, That a trial meeting be held for the Southeastern Region in Atlanta, Ga., at a time deemed suitable by the Board of Trustees and the headquarters staff in cooperatoin with the Medical Association of Georgia.

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Dr. Woodruff L. Crawford, Chairman, Section on Pediatrics, read the following report, which was adopted:

American Medical Association Regional Meetings (Resolution No. 16).—This resolution introduced for the Medical Association of Georgia requests the institution of a series of small regional two-day meetings to supplement the interim meetings. The Trustees, the Law Department, the Public Relations Department, and others confirm the fact that the American Medical Association is eager to offer assistance in furnishing speakers, material, and other support for any county, state, or regional meeting, if asked.

Your reference committee favors meetings of this type, but recommends that no action be taken for the reasons detailed.

No. 17. Resolution on Sears-Roebuck Foundation

Dr. Charles H. Richardson Sr., for the Medical Association of Georgia, introduced the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The Sears-Roebuck Foundation, through a generous grant, in conjunction with the American Medical Association served the medical profession and the public at large with research and development in health activities; and

Whereas, The Sears-Roebuck Foundation has specifically established a broad program in a "Plan of Assistance to Physicians Establishing Medical Practice Units"; and

Whereas, The Sears-Roebuck Foundation prepared and distributed "A Planning Guide for Establishing Medical Practice Units" to augment its plan of assistance; and

Whereas, The Sears-Roebuck Foundation has rendered a sizeable amount of financial assistance to medical practitioners throughout the United States under this plan during 1955 and will continue its assistance; therefore be it

Resolved, That the House of Delegates of the American Medical Association commend the Sears-Roebuck Foundation for this aid to medical practitioners and the people of this country.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Joseph C. Griffith, Chairman, Wisconsin, submitted the following report, which was adopted:

Resolution No. 17 commends the Sears-Roebuck Foundation for its aid to medical practitioners and the people of this country. Your committee favors the adoption of this resolution and suggests that a summary of a year's accomplishment be reported in a suitable issue of The Journal.

No. 18. Resolutions on American Medical Education Foundation and American Medical Association Dues

Dr. Spencer A. Kirkland, for the Medical Association of Georgia, introduced the following resolutions, which were referred to the Reference Committee on Reports of Board of Trustees and Secretary:

Whereas, It has been previously approved and recommended by the Council of the Medical Association of Georgia that individual association members be strongly urged to contribute *voluntarily* to the American Medical Education Foundation; and

Whereas, The financial support of AMEF has been left to the individual discretion of each physician on a voluntary basis; therefore be it

Resolved, That the House of Delegates of the American Medical Association go on record in favor of this financial support of AMEF on a voluntary basis by individual physicians; and be it further

Resolved, That the House of Delegates of the American Medical Association opposes any compulsory assessment for this purpose and as such also opposes any raise in American Medical Association dues for allocation to the AMEF Funds.

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Dr. Woodruff L. Crawford, Chairman, Section on Pediatrics, submitted the following report, which was adopted:

American Medical Association Dues and American Medical Education Foundation Support (Resolution No. 18).—This resolution introduced for the Medical Association of Georgia was considered. Your reference committee feels that the individual state medical associations should decide how their members will support the American Medical Education Foundation, and therefore recommends no action be taken on this resolution

No. 19. Resolutions on Automobile Safety

Dr. Charles H. Richardson Sr., for the Medical Association of Georgia, introduced the following resolutions, which were referred to the Reference Committee on Hygiene, Public Health, and Industrial Health:

WHEREAS, The medical profession has and must continue to fulfill its pledged responsibility to maintain and improve the health of the general public, and

WHEREAS, The medical profession has made outstanding advances in the art and science of medicine to the extent that the public in these United States enjoys the highest standards of health ever attained; and

WHEREAS, There is yet a medical problem of major proportion facing the profession which has been neglected, and

WHEREAS, This medical problem, the killing and maiming of people on our highways, effects more persons than does all illness known today, therefore be it

Resolved, That the House of Delegates of the Medical Association of Georgia requests the American Medical Association to lend every effort, morally and financially, to combat this problem through its Board of Trustees, councils and committees, and its constituent state medical associations, and be it further

Resolved, That the American Medical Association conceive and endorse a comprehensive program of automobile safety during 1956-57, and report to the House of Delegates at the 1957 session in New York City, and be it further

Resolved, That the American Medical Association request each constituent state medical association to set up a committee on automobile saftey for similar purposes during 1956-57.

REPORT OF REFERENCE COMMITTEE ON HYGIENE, PUBLIC HEALTH, AND INDUSTRIAL HEALTH

Dr. Martyn A. Vickers, Chairman, Maine, presented the following report, which was adopted.

Automobile Safety.—Your reference committee recommends this resolution with the following changes involving the "resolves:"

Resolved, That the traffic safety committee of the American Medical Association contact the various state societies suggesting the establishment of traffic safety committees on a state and local level and that it offer whatever help the various state and local societies need in establishment of these committees, and be it further

Resolved, That the American Medical Association suggest that a cooperative effort be suggested with the various local committees established by the White House Conference on Safety, and be it further

Resolved, That if and when feasible a national meeting of the American Medical Association committee on traffic safety be held to implement the responsibilities of the medical profession in automobile safety

No. 20.

The Speaker announced that Resolution No. 20 had been withdrawn.

No. 21. Resolutions on Department of Civil Defense Disaster Control

Dr. William F. Costello, for the Medical Society of New Jersey, introduced the following resolutions, which were referred to the Reference Committee on Medical Military Affairs:

WHEREAS, We are informed by the military that the next war in this "atomic age" will be directed against the civilian population as well as against military objectives, and

WHEREAS, The government of the United States through the Civil Defense Administration has not made proper and adquate provision for the medical needs of the civilian population in the event of an attack of such magnitude, and

WHEREAS, The personnel, facilities, and equipment already provided or contemplated can be used as readily in civil disaster caused by acts of God in our country as for catastrophy caused by enemy action, and

WHEREAS, The over-all direction of rescue and relief efforts extending over many states is a matter for federal direction and transects state boundaries, and

WHEREAS, There is no federal agency at present directly charged with the protection or relief of the civilian population affected by such natural disaster, now therefore be it

Resolved, That the establishment of a Department of Civil Defense Disaster Control in the Department of Defense of the United States be recommended, that the director of this department be given status equal to the status of the directors of the Army, the Navy, or the Air Force, and that this Department of Civil Defense Disaster Control be directly charged with the protection, rescue, and relief of the civilian population of this country from the effects of natural disaster as well as the effects of disaster resulting from enemy action, and be it further

Resolved, That the American Medical Association make its voice heard to the Congress of the United States as a proponent of this plan.

REPORT OF REFERENCE COMMITTEE ON MEDICAL MILITARY AFFAIRS

Dr. William C. Chaney, Chairman, Tennessee, submitted the following report, which was adopted:

Your reference committee has carefully reviewed Resolution No. 21 introduced by the New Jersey delegation. That resolution seeks to establish a separate Department of Civil Defense Disaster Control within the Department of Defense, having coequal status with the Departments of the Army, Navy, and Air Force.

Your committee favors the broad objective of strengthening the federal civil defense program. However, your committee notes that legislation is currently pending in the Congress which, if enacted, would increase the status and strengthen the program. Moreover, a subcommittee of the House Government Operations Committee is and has been conducting extensive hearings on all aspects of civil defense. Your committee believes it would be more appropriate to concentrate the efforts of the Association on the medical aspects of disaster preparedness as outlined in supplementary report I of the Board of Trustees. Your committee recommends that Resolution No. 21 not be adopted.

No. 22. Resolution on Electoral Reform

Dr. George D. Johnson, for the South Carolina delegation, introduced the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, The foundation of American freedom and liberty is dependent in large measure upon the right of citizens in their respective states to select the executive heads of government, and

WHEREAS, Under the present system of selecting the President and Vice President of the United States the entire electoral vote of each state is given to the candidate receiving a plurality of the votes in such state, thereby disenfranchising all voters supporting the losing candidate in each state, and

WHEREAS, Under such a system the votes of citizens do not have equal weight and value and as a result many are effectively deprived of an equal and just voice in the selection of the President and Vice President, and

WHEREAS, Bloc-voting minority groups in big city states which can throw the entire electoral vote of their respective states to one candidate or another are wielding an influence disproportionate to their numbers on the selection of candidates and party platforms and on the policies and programs of officials responsible to the entire nation, and

WHEREAS, The influence of minority bloc-voting groups is growing as populations shift from the smaller and rural states to the big city states and threatens established constitutional freedoms, individual liberty, and the capitalistic free enterprise system, and

WHEREAS, The need for a change has been recognized in a sample poll of the people by a two to one majority and by expressions by more than two-thirds of the Senate during the debate on this subject during the past year, and

WHEREAS, Of the numerous methods proposed, the so-called district plan calls for only a slight change in the Constitution and is a great improvement over the present system and would serve the purpose of improving the climate for the preservation of the Republic and the freedom and liberty of its people, and

WHEREAS, This method would encourage candidates from all sections of the nation to seek the high offices in the land, and encourage the nominees of both political parties to make every section of the country an area of contest, now therefore be it

Resolved, That the House of Delegates of the American Medical Association approve in principle the district method of electoral reform and encourage the members of Congress who are struggling with this complex subject to proceed as rapidly as practicable.

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

Dr. Willis H. Huron, Chairman, Michigan, presented the following report, which was adopted:

Resolutions Nos. 22 and 29.—Your committee considered these resolutions jointly and feels that because of the magnitude of the problem involved, they should be referred to the Board of Trustees for clarification and disposition.

No. 23. Resolution on Governmental Purchase of Salk Vaccine

Dr. Kenneth C. Sawyer, for the Colorado State Medical Society, introduced the following resolution, which was referred to the Reference Committee on Hygiene, Public Health, and Industrial Health:

WHEREAS, Distribution of free Salk vaccine has been extended to include many more than the indigent group, thus constituting unnecessary government spending; and

WHEREAS, Distribution by government agencies has resulted in a bizarre, unscientific, and inequitable administration of vaccine, thereby casting disrepute on the private doctors of medicine and consternation, concern, and confusion on the public; and

WHEREAS, Those pharmaceutical houses which cooperated in the plan at great expense and trouble are being denied a reasonable recovery of their investment by the almost total purchase of the vaccine supply by the government; and

WHEREAS, A much wider and more adequate protection of the public would be attained through regular chanels of distribution; now therefore be it

Resolved, That the American Medical Association requests the United States Government to return the general wholesale and retail purchase of Salk anti-poliomyelitis vaccine to normal, free enterprise, commercial channels and to cease governmental purchase of the vaccine in other than those amounts needed by the Public Health Service for essential public health needs and for distribution to the indigent population of the nation.

REPORT OF REFERENCE COMMITTEE ON HYGIENE, PUBLIC HEALTH, AND INDUSTRIAL HEALTH

Dr. Martyn A. Vickers, Chairman, Maine, read the following report, which was adopted:

Governmental Purchase of Salk Vaccine.—This Resolution No. 23 brings again to the fore governmental interference in medical practice which is contrary to the principles of the American Medical Association, and your committee therefore recommends the passage of the resolution with the deletion of the third "whereas." This is being deleted as your committee does not feel that it is the business of the American Medical Association to interfere in the financial and commercial aspects of pharmaceutical houses. Your committee further believes that the words "free enterprise" in the "resolve" should be deleted, so that the "resolve" will read as follows:

Resolved, That the American Medical Association requests the United States Government to return the general wholesale and retail purchase of Salk anti-poliomyelitis vaccine to normal, commercial channels and to cease governmental purchase of the vaccine in other than those amounts needed by the Public Health Service for essential public health needs and for dis- ·bution to the indigent population of the nation.

No. 24. Resolution on Guiding Principles for Evaluating Management and Union Health Centers

Dr. Kenneth C. Sawyer, for the Colorado State Medical Society, introduced the following resolution, which was referred to the Reference Committee on Insurance and Medical Service:

WHEREAS, The free choice of physician by the the patient has long been fundamental in the Principles of Medical Ethics of the American Medical Association; and

WHEREAS, The Principles of Medical Ethics permit the interjection of a third party between physician and patient as having a valid interest *only* in relation to occupational disabilities; and

WHEREAS, The language of the "Guiding Principles for Evaluating Management and Union Health Centers," published in December, 1955, over the *signature* of the American Medical Association, contains wording that can be *construed* as an abandonment by our Association of this principle of free choice of physician, since these Guides are for health centers which will care for nonoccupational illnesses and for *workers'* dependents as well as for occupational disabilities; and

WHEREAS, This constitutes a conflict between the *Principles of Medical* Ethics and the recently published Guides which must be resolved in favor of the *Principles of Medical Ethics*; now therefore be it

Resolved, That the Council on Medical Service and the Council on In- Health are jointly directed *to reconsider* the aforesaid manual their joint Committee on Medical Care for Industrial Workers, to the said Guides that they conform completely to the *Principles* of ies, and to report to the House of Delegates.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

Dr. John K. Glen, Chairman, Texas, submitted the following report, which was adopted:

Resolution No. 24 on Guiding Principles for Evaluating Management and Union Health Centers.—Your committee is cognizant of the fact that the Principles of Medical Ethics is being revised but, even so, can see no reason why this resolution should not receive your approval, and recommends it.

No. 25. Resolution on Disapproval of Internship "One-Quarter Rule"

Dr. Gerald D. Dorman, for the Medical Society of the State of New York, introduced the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

WHEREAS, The House of Delegates of the American Medical Association in June, 1955, approved a report of its Reference Committee on Medical Education and Hospitals to the effect that the "one-quarter rule" be established in hospitals approved for internships, and that if a hospital does not obtain one-quarter of its quota of interns for two years in succession that the internship approval be withdrawn; and

WHEREAS, Such a rule is not necessarily related to the quality of the internship program; and

WHEREAS, Such a rule could give undue advantage to the larger training hospitals; now therefore be it hereby

Resolved, That the aforesaid approval be rescinded.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION AND HOSPITALS

Dr. George S. Klump, Chairman, Pennsylvania, read the following report, which was adopted:

Resolution No. 25.—This resolution was supported by only two members at the hearing. Your committee reviewed the theoretical application of the "one-quarter rule" for the successive years 1953-1954, 1954-1955, and 1955-1956. Any requirement of this nature must be under constant review and subject to prompt revision as experience with its operation may dictate. Since its effect cannot be measured until it has been in operation, your reference committee recommends that Resolution No. 25 be not adopted.

No. 26. Resolution on Use of Radium or Radioactive Isotopes

Dr. Carl A. Lincke, Ohio, introduced the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The House of Delegates of the American Medical Association in June, 1951, adopted a resolution supporting a recommendation that the use of radium and radioactive isotopes be under the supervision of one certified in radiology or therapeutic radiology; and

WHEREAS, The states license physicians to use all drugs and agents useful in the diagnosis and treatment of diseases; and

WHEREAS, The boards of certification are private organizations without legal status to regulate the practice of medicine; and

WHEREAS, No drug or agent that is useful or may become useful in the diagnosis or treatment of diseases should be limited in its use to physicians with special interests or in limited fields of practice; and

WHEREAS, Radioactive *isotopes* have already been proved and are continuing to be proved by physicians of widely diverse *interests to* have extraordinarily wide and unique applications as clinical biochemical tools and drugs that are useful *in the diagnosis* or treatment of diseases; and

WHEREAS, Physicians will not wish to engage in any practices that remove incentive or stifle *initiative to discover new* applications or to improve existing applications of radioactive isotopes in the diagnosis or treatment of diseases; and

WHEREAS, The history of medicine is replete with examples of advances in the art and science of medicine made by *individual physicians* regardless of their special interests and training; and

WHEREAS, The *new* thoughts and discoveries that originate in the minds of men are often *revealed* in the nature of acts of God and as manifestations of divine inspiration; and

WHEREAS, The House of Delegates of the Ohio State *Medical* Association is on record recommending that the *action* of the American Medical Association House of Delegates in June, 1951, *should* be rescinded; now therefore be it

Resolved, That the action taken by the *House* of Delegates of the American Medical Association in June, 1951, is *hereby rescinded* to remove any barrier which may now exist to the use of radium or radioactive isotopes by any physician consonant with the practices established among his fellow physicians of his community.

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

Dr. Joseph C. Griffith, Chairman, Wisconsin, presented a report regarding Resolution No. 26. After discussion and amendment, the House of Delegates adopted the following: "That the Speaker of the House of Delegates appoint a committee to study the use of radioactive isotopes and other materials and to report to the Board of Trustees prior to the next clinical meeting at Seattle."

No. 27. Resolution on Joint Commission on Hospital Accreditation

Dr. L. Howard Schriver, Ohio, introduced the following resolution, which was referred to the Reference Committee on Medical Education and Hospitals:

WHEREAS, The objective of the Joint Commission on Accreditation of Hospitals is to enable physicians and hospitals to aid each other in the delivery of the best possible medical care to patients; and

WHEREAS, Certain regulations enacted by the Joint Commission on Accreditation of Hospitals and their interpretation by representatives of the Joint Commission make it unnecessarily difficult to achieve the above objective; and

WHEREAS, There is reason to believe that certain unnecessary requirements are leading to an increase in hospital costs without a commensurate increase in the quality of professional and hospital care of patients; now therefore be it

Resolved, That the House of Delegates of the American Medical Association recommends:

(1). That the Joint Commission on Accreditation of Hospitals revise its standards in order to provide more discretion locally for medical staffs and hospital authorities to make appropriate adjustment of their organization activities to fit the hospital's particular needs and those of the community;
